

DEPFET Mini-matrix Setup

C. Oswald, J. Scheirich

Charles University in Prague
Institute of Particle and Nuclear Physics

6th International Workshop on DEPFET Detectors and Applications

7-9 February 2011

LVR-Landes Museum Bonn

Outline

- Introduction
- System Upgrade
- Overview of Software
- Source Spectra
- Noise Performance
- Summary & Plans

Introduction

- **Mini-matrix Setup**

- System for measurement of the DEPFET mini-matrices

- 48 pixels active

- 8 drain channels

- Readout in parallel

- 6 gate channels

- Addressing the double-rows

- Slow readout

- Low noise

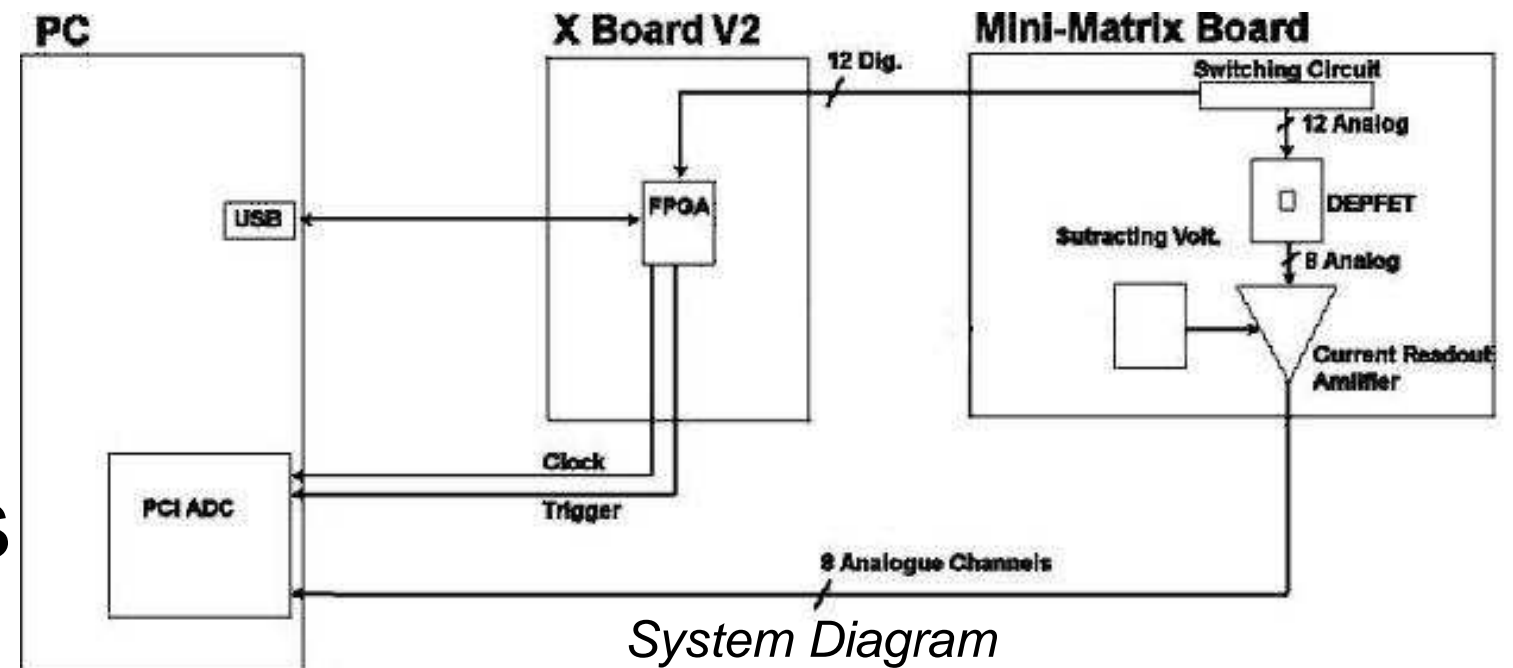

Photo of a Mini-matrix

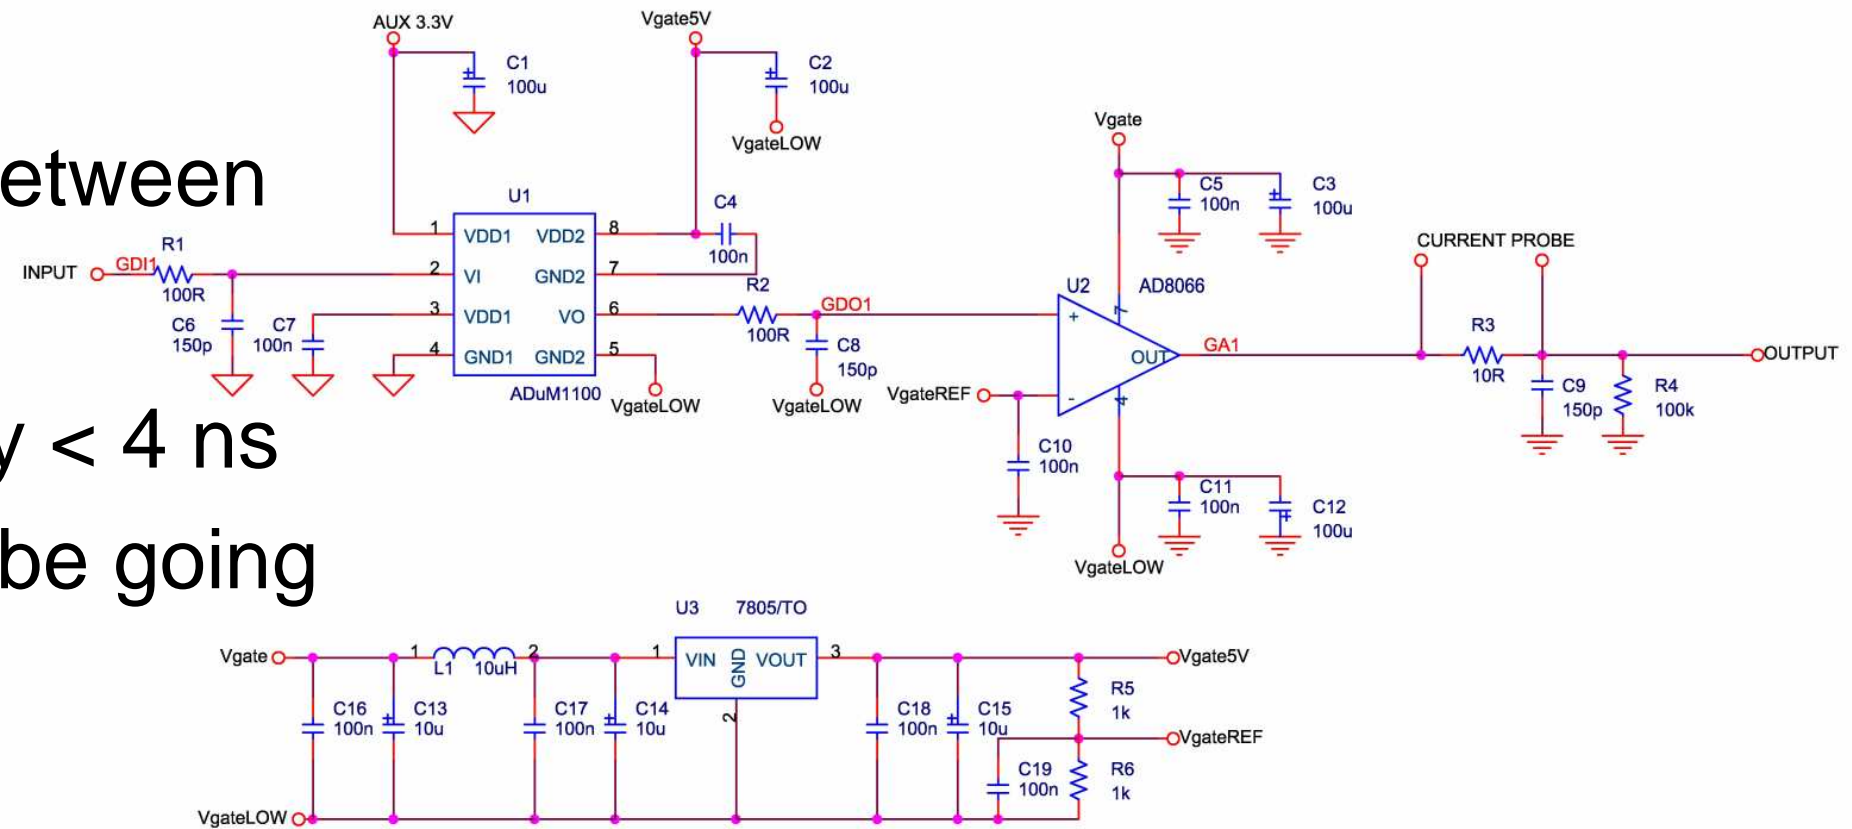

Mini-matrix Setup

System Upgrade - Switcher

- Smooth signal
- Amplitude difference between channels < 3 mV
- Repetition time stability < 4 ns
- Gate/Clear current probe going to be implemented

One Switcher Channel

Gate signals

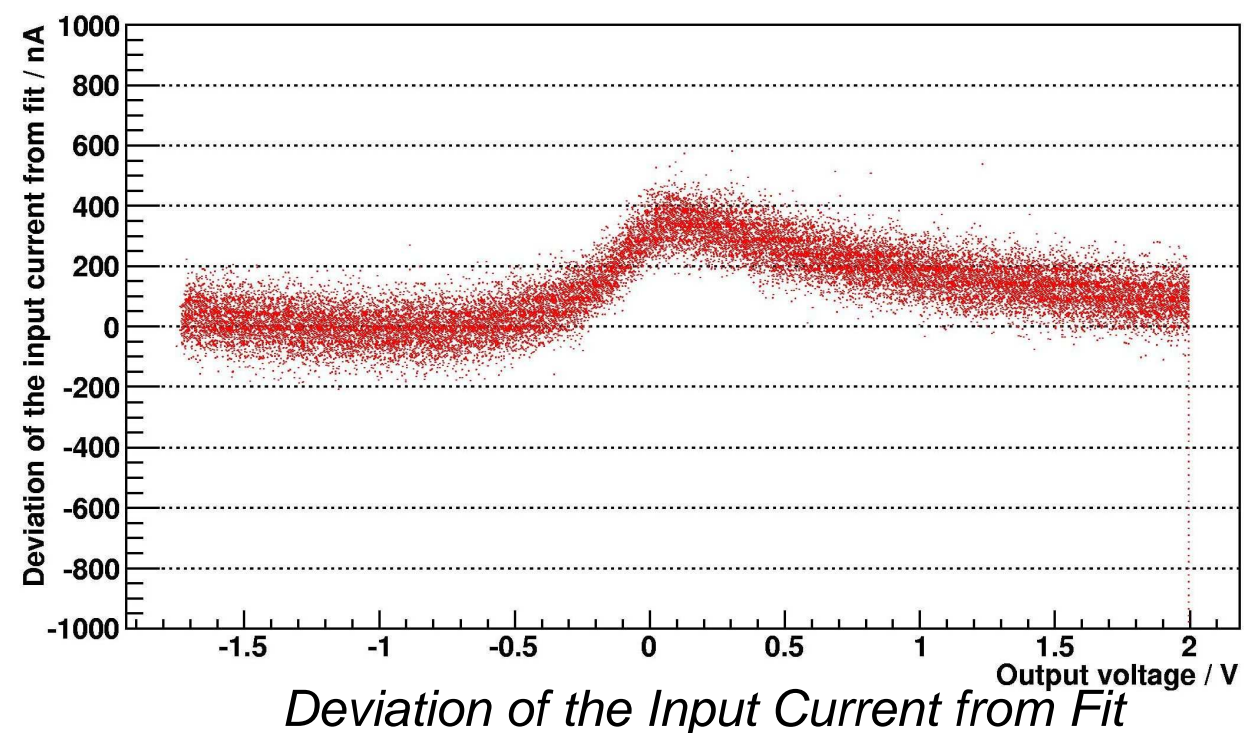

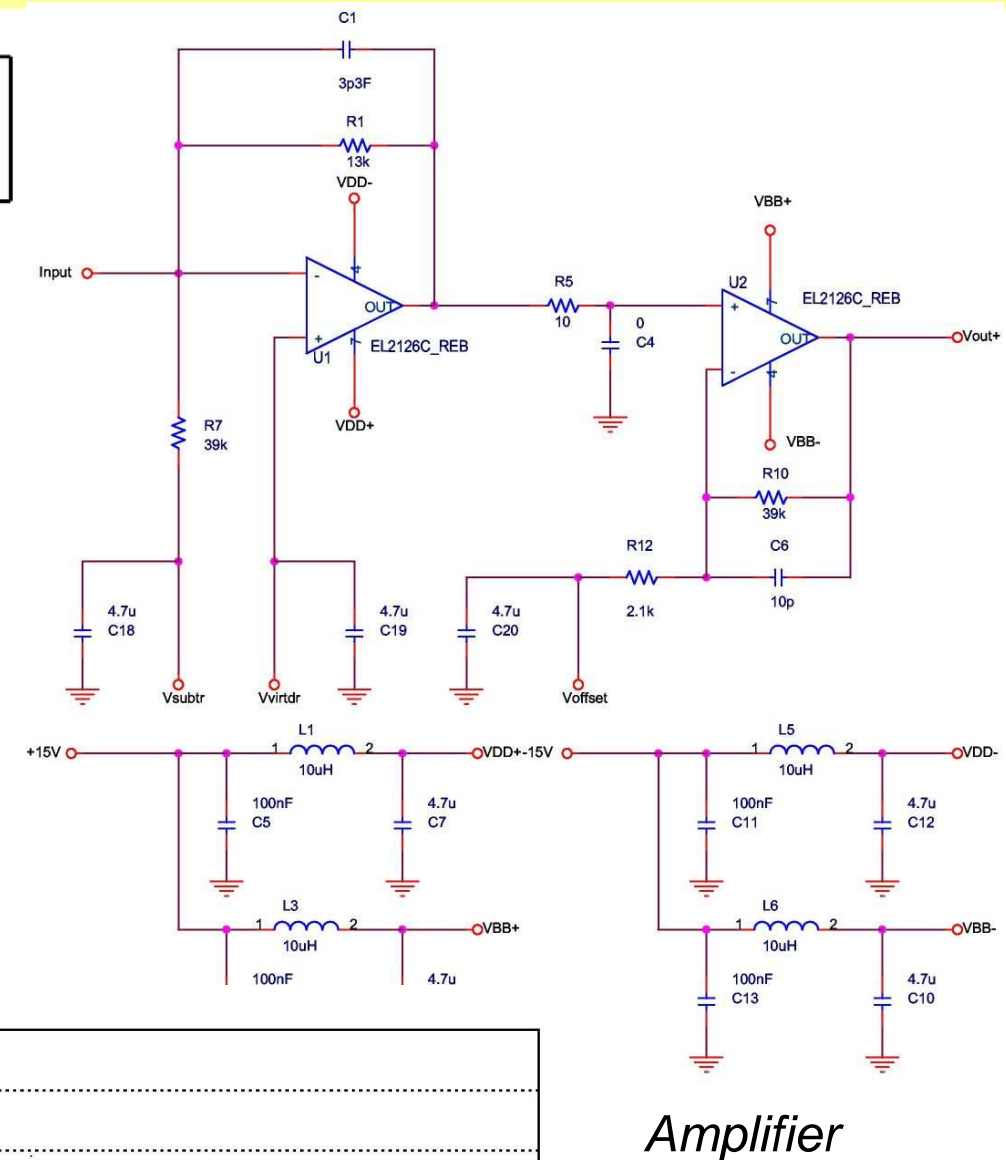

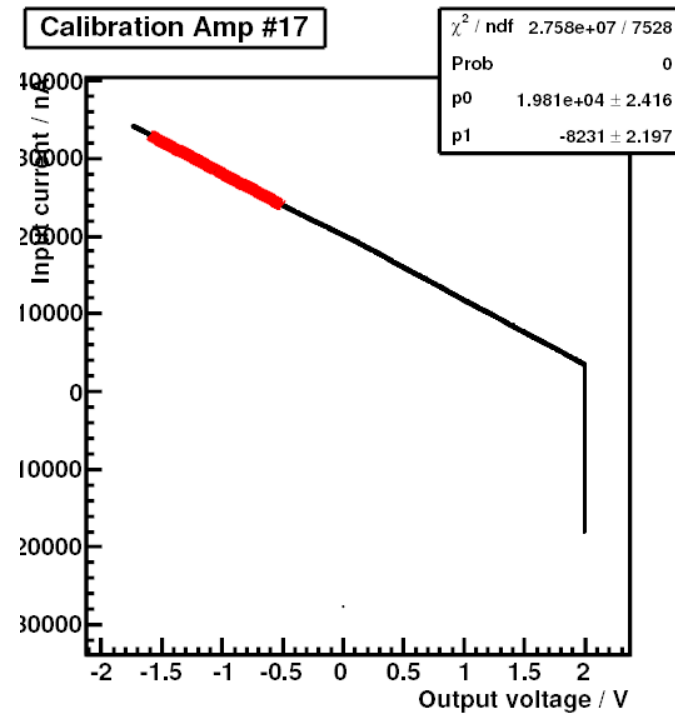

Edge of gate

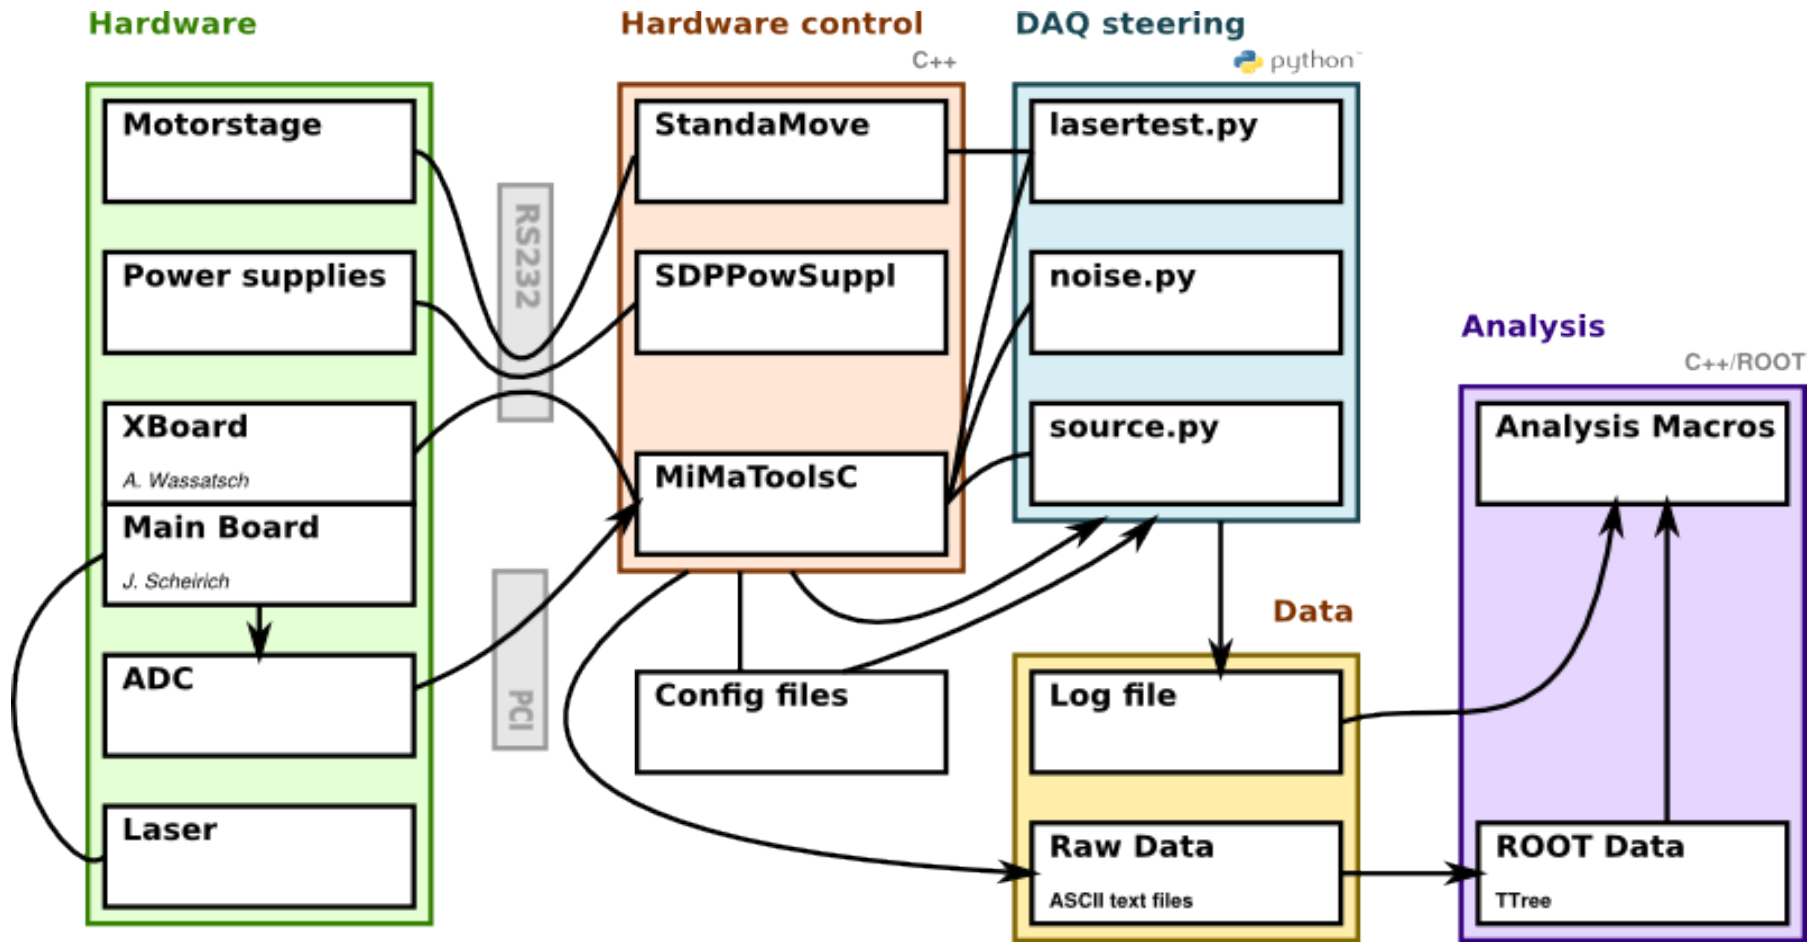

System Upgrade - Amplifiers

- Optimization for low noise and distortion
 - 3rd stage was removed
 - Feedback was modified
- Calibration
 - Nonlinearity when amp is crossing “0” -> operation range shifted to negative values
 - Nonlinearity in the op. range < 0.15 % but it is ~ 15 nA in absolute scale
 - Higher precision might be achieved by software correction

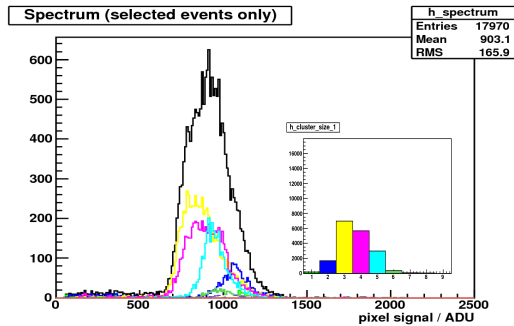

Overview of the software package

Summary

Source test

Noise measurement

Laser test

MiMa Setup

Raw data = full scope signal

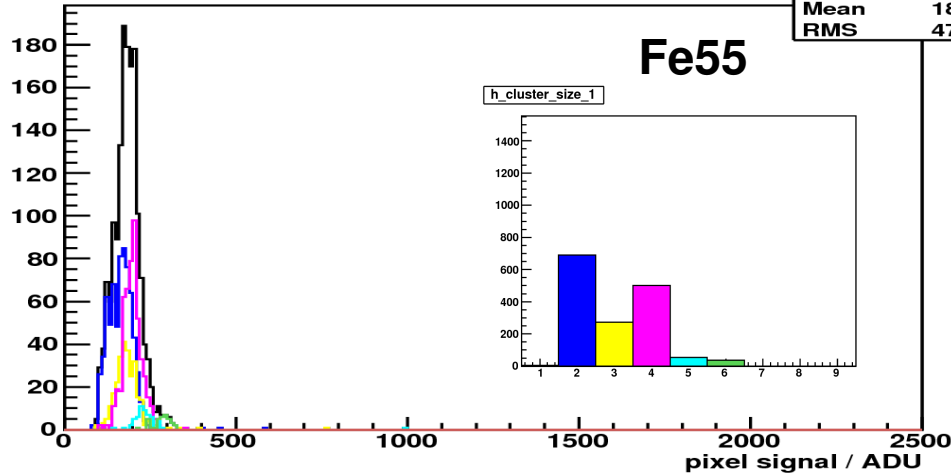

Flexible readout sequences

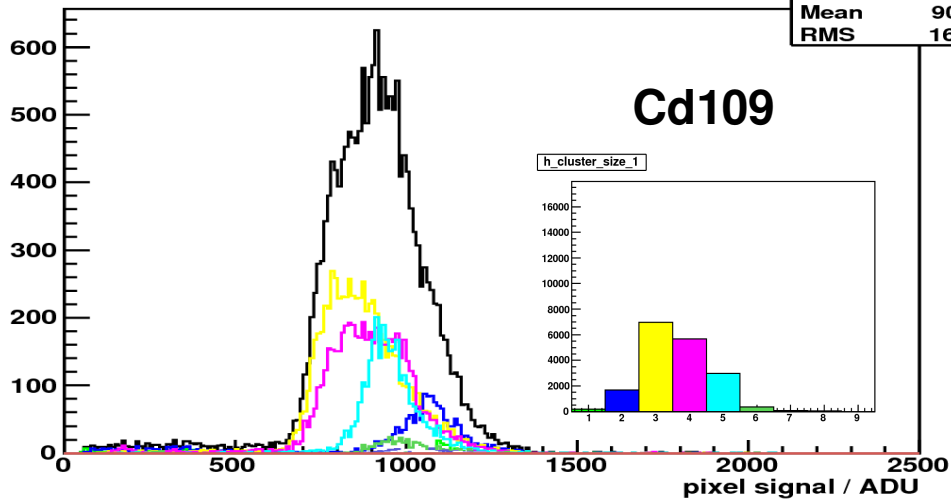

Spectra

Spectrum (selected events only)

Spectrum (selected events only)

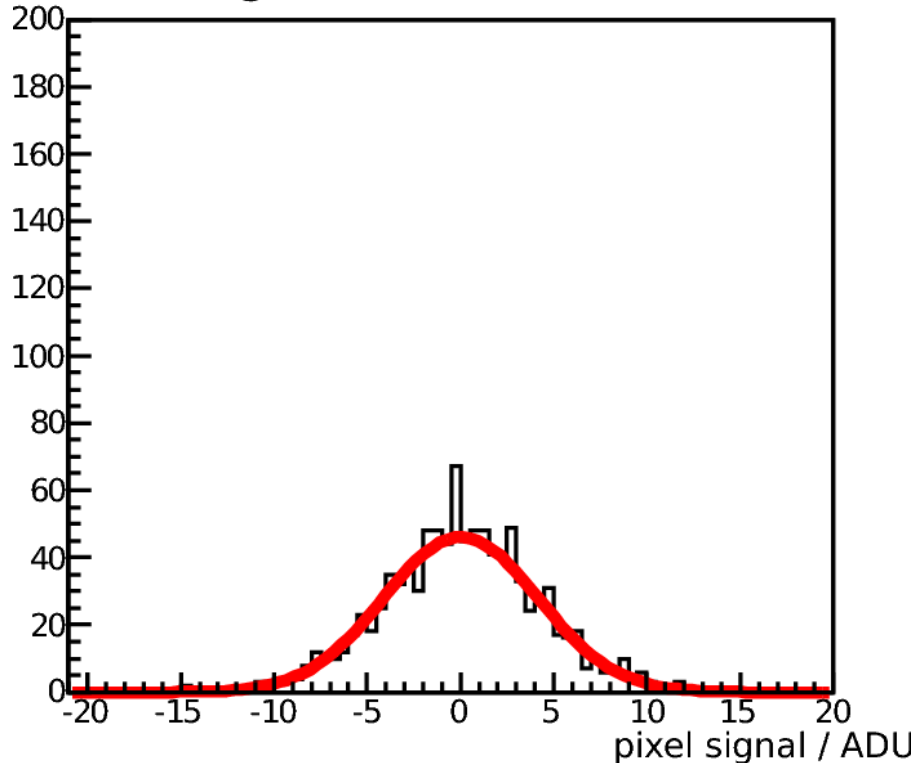

- Significant differences in charge collection depending on cluster size
- Estimation of the internal amplification:

$$g_q = \frac{dI}{dQ} \approx \frac{\Delta I}{\Delta Q} = 269...419 \text{ pA/e}^-$$

Noise

sigma 4.138 ± 0.119

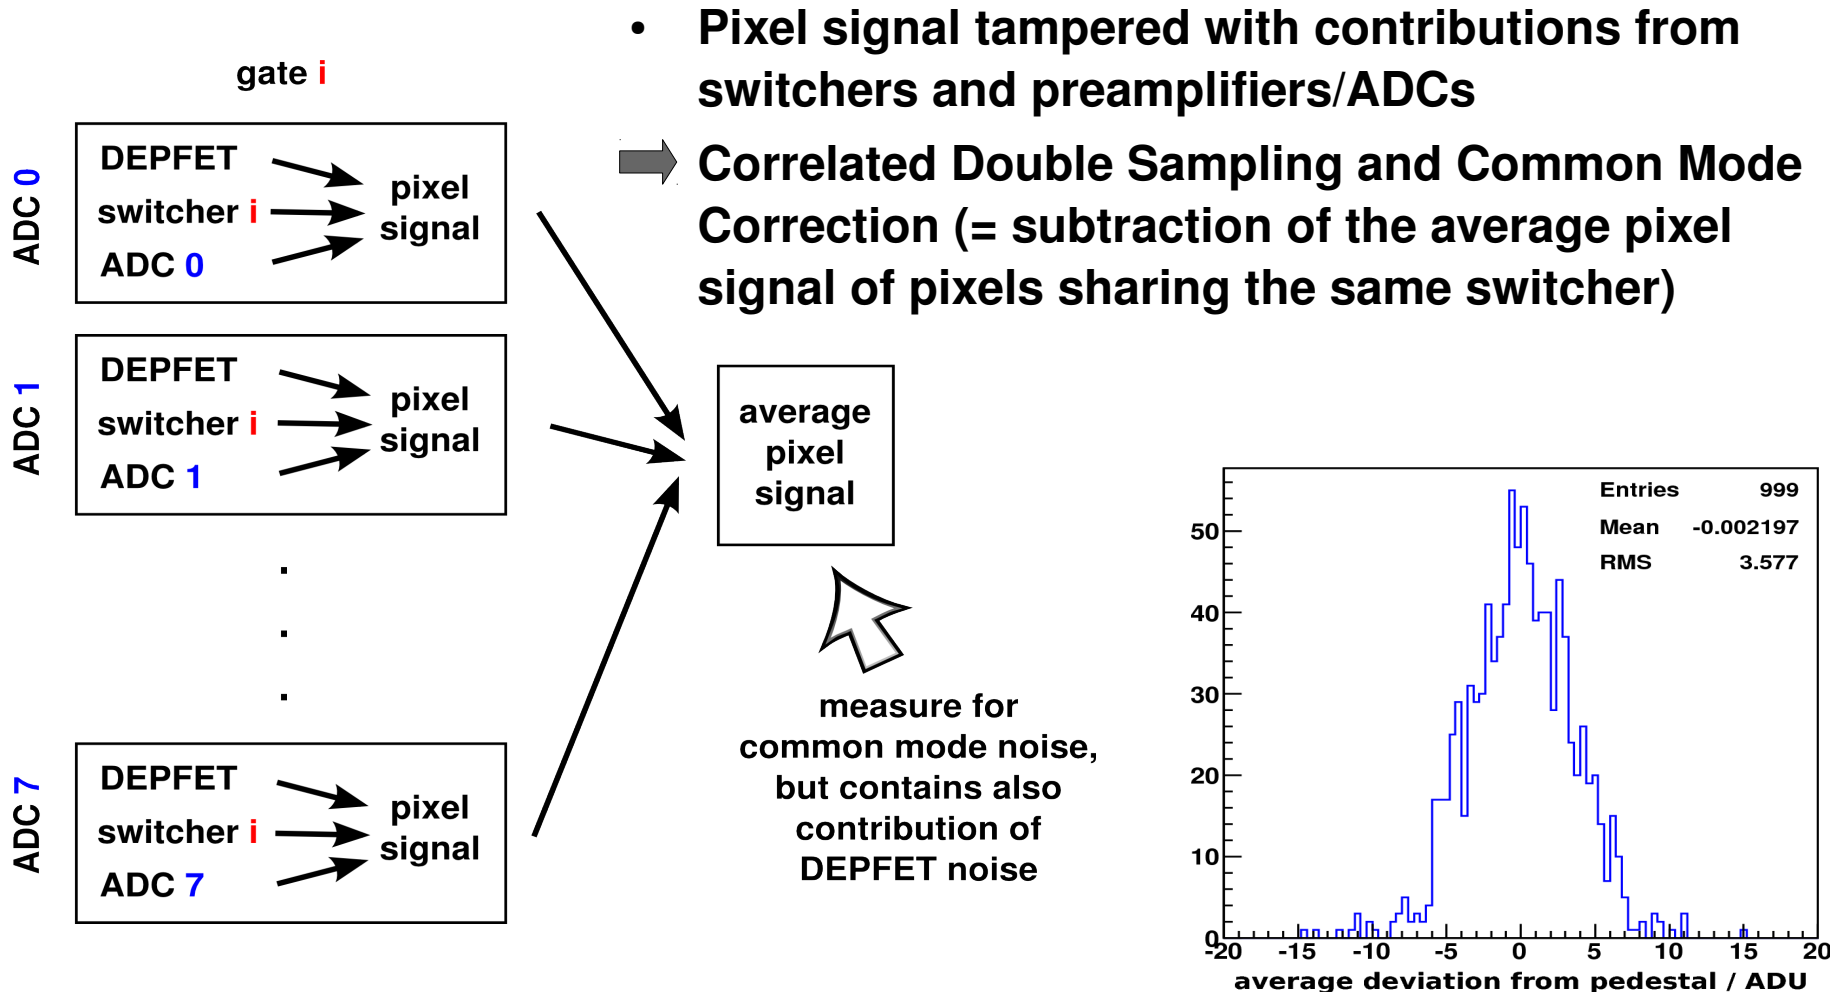

- Acquisition of 1000 frames in black box
- Noise distribution = distribution of pedestal subtracted pixel signal
- Does not correspond to the noise of a spectrum (see previous slide!)

$$4.138 \text{ ADU} = 8.516 \text{ nA} \\ = 20 \dots 32 \text{ e}^-$$

Contributions to the pixel signal

Common mode correction

common mode corrected pixel noise

- CM corrected distribution is not Gaussian anymore
- Overcorrection results in a too optimistic noise estimation
- Correction factor $\sqrt{n/(n-1)}$ assuming similar noise in all pixels
- CM corrected pixel noise:

$$\begin{aligned}\sqrt{8/7} \times 2.00 \text{ ADU} &= 2.14 \text{ ADU} \\ &= 4.41 \text{ nA} \\ &= 11...16 \text{ e}^{-}\end{aligned}$$

The common mode correction cannot be applied to measurements with pixel signal other than noise (source, laser) - not enough pixels

Status & Plans

- **Hardware: amplifiers & switchers upgraded to improve noise properties**
- **Software: System ready to perform all standard measurements**
- **Hardware update: measurement of gate/clear current**
- **Software update: PXD6 matrices**
- **2 new setups in preparation for MPI + LMU**

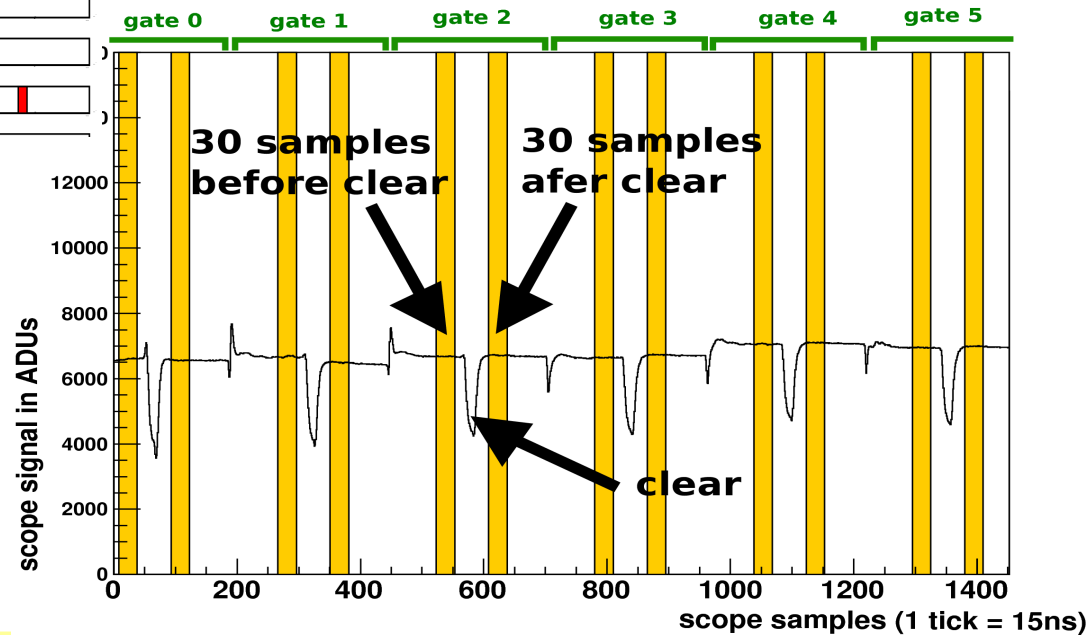

THANK YOU FOR YOUR ATTENTION!
