

# Development of a straw-tube chamber prototype for the inner detector of a future $e^+e^-$ collider experiment

Julia Okfen

ATLAS Muon Group (Max Planck Institute for Physics)

DPG Frühjahrstagung – Göttingen (04.04.2025)

# Future Circular $e^+e^-$ Collider - FCCee

- Planned after HL-LHC with a circumference of 91,2 km

## Higgs Factory:

- $\sqrt{s} = 240$  GeV
- Higgs radiation drives requirements for the inner detector
- Precision measurement of the total width of Higgs
  - ✓ Know initial state with good accuracy and final state consists of two bodies
    - Measure momentum of Z → Calculate recoil mass of H → total width of H  
→ model independent measurement (no decay products of H)
- Beam energy known down to 0.1% → want to achieve same resolution for Z

measurement →  $\frac{\sigma(p_T)}{p_T} \sim 0.1\%$  for  $p_T = 50$  GeV

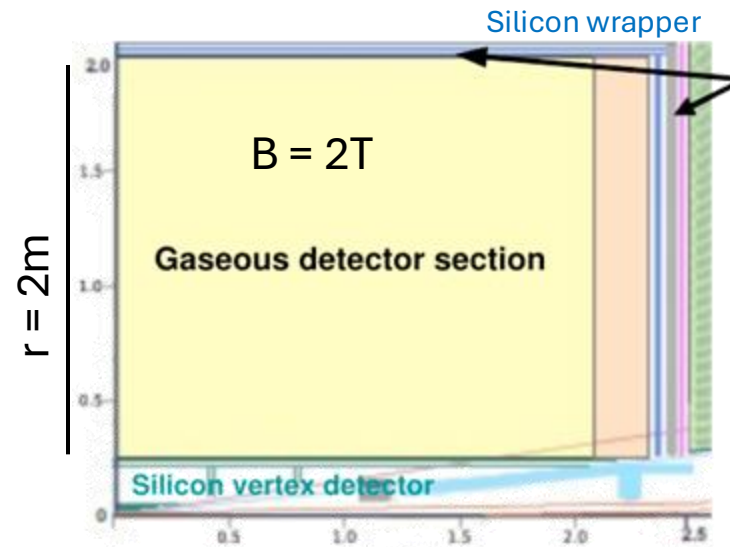

# Setup & requirements for the inner detector

All silicon detector

<https://agenda.linearcollider.org/event/10211/contributions/53543/attachments/39282/61939/FCC-ee-Detectors-20240115.pdf>

Silicon + gaseous detector

[https://indico.cern.ch/event/1408681/contributions/6107963/attachments/2946580/5178215/MPP\\_straw\\_dev.pdf](https://indico.cern.ch/event/1408681/contributions/6107963/attachments/2946580/5178215/MPP_straw_dev.pdf)

Contributions to momentum resolution:  
position resolution  
multiple scattering (MS)

	Advantages	Disadvantages
Silicon detectors	Excellent position resolution ( $5 \mu\text{m}$ )	Material budget $\rightarrow$ MS
Gaseous detectors	Low material budget Particle identification (often w. He)	Position resolution limited ( $100 \mu\text{m}$ )

# Inner detector – gaseous volume

## Drift chamber:

- Gaseous volume equipped with  $\sim 350.000$  wires

## Straw tubes

- Drift tube with wall thickness of  $\sim \mu m$

## Advantages of a Straw Tube Chamber

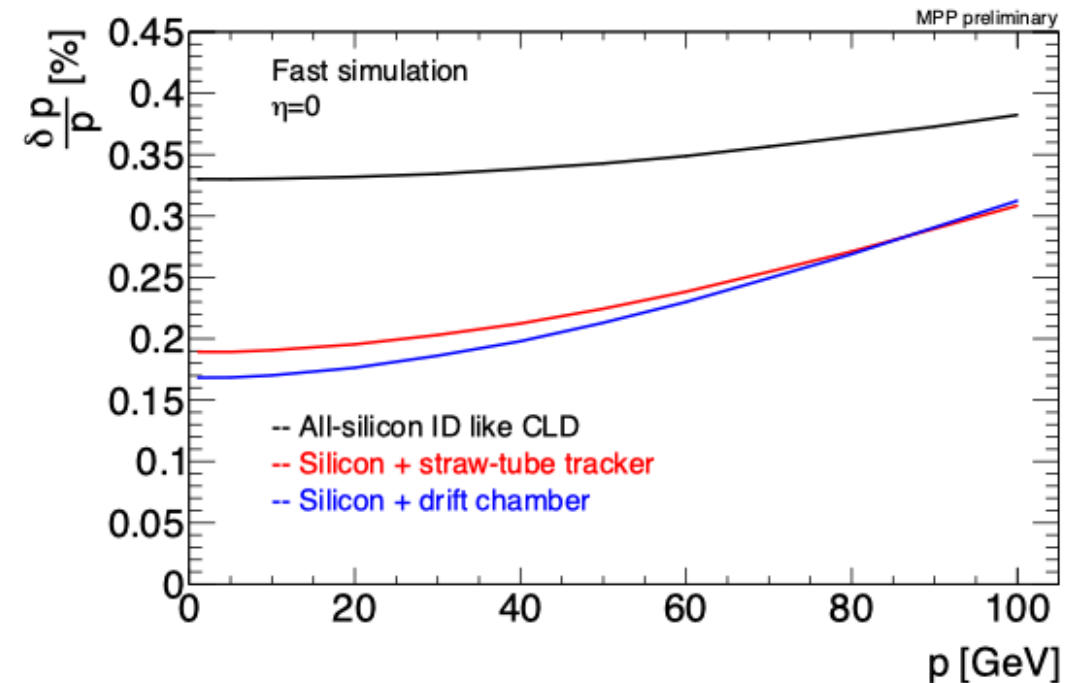

- ✓ Each tube is an individual detector unit
  - A single broken wire affects only the corresponding tube, but not whole tracker
- ✓ Possibility to use different gases in different tubes

# Comparison of the momentum resolution

Gaseous detector	Drift chamber	Straw tube
Material budget	$2.6 \cdot 10^{-5} X_0$	$9 \cdot 10^{-5} X_0$

- The radiation length per layer is comparable for both gaseous options
- All silicon detector: hard to achieve a resolution  $< 0.3\%$
- Momentum resolution of both gaseous options comparable

# Small muon drift tubes (sMDT)

- Based on sMDTs, we are developing a straw tube prototype
- MPP developed sMDTs for the ATLAS Muon Upgrade

## sMDT parameters

Wall thickness:	0.4 mm
Tube radius:	7.1 mm
Wire radius:	50 $\mu\text{m}$
Spatial resolution:	$\sim 100 \mu\text{m}$
Operating gas:	Ar/CO <sub>2</sub> (93/7)
Operating voltage:	2730 V
Operating pressure:	3 bar
Mechanical precision of whole chamber	10 $\mu\text{m}$

[https://www.atlas.mpp.mpg.de/ftp/outgoing/sMDT/BIS/MuonPhase2IDR/sMDT/sMDTIDR/sMDT\\_0.pdf](https://www.atlas.mpp.mpg.de/ftp/outgoing/sMDT/BIS/MuonPhase2IDR/sMDT/sMDTIDR/sMDT_0.pdf)

# Straw Tube prototype

## Straw parameters

Walls made of thin mylar double coated with Al

Thickness:  $\sim \mu\text{m}$

Tube radius: 7.1 mm

Wire radius:  $50 \mu\text{m}$

Operating gas: He/iC<sub>4</sub>H<sub>10</sub> (90/10)

Operating voltage: 1624 V

Operating pressure: 1050 mbar

- Producing 48 Straw Tubes of 1.45m length (+ 7 spares) → 2 layers with 6 x 4 Straws
- Need of a support structure bc. of flexible tube wall

# Straw Tube prototype - endplug

- Reuse electronics and gas supply system from ATLAS sMDTs
- The endplugs needed to be adapted for the purpose of gluing instead of crimping
- Goal: gas tightness and electric contact

- Glueing channel beneath the surface of the endplug
- Inner ring: mechanically good glue
- Outer ring: electrically conducting glue

## Glueing clamp

- O – rings surrounding the glueing channels
- Three-part clamp to prevent creases in the straw wall

# Straw Tube production - tests

Tests conducted	Results
<p><b>Gas leakage test</b></p> <p><u>Operating conditions</u> Ar/CO<sub>2</sub> (93/7) at a pressure of <math>p = 1100</math> mbar</p>	No leaks detected by sniffing Argon
<p><b>Resistivity</b></p> <p>Measurement with digital voltmeter to check if the electrical glueing was successful</p>	✓
<p><b>Dark current</b></p> <p><u>Operating conditions</u> Ar/CO<sub>2</sub> (93/7) at a pressure of <math>p = 1100</math> mbar</p>	<p>Goal: current below 2 nA</p> <p>Result: tested up to 2.73 kV which corresponds to a gas gain of 380.000.000 → within the limit</p>

# Helium-isobutane studies

As already anticipated, we want to use Helium to fill the Straw tubes

- First experimental cosmic ray tests can already be conducted without the straw tube chamber by using a **sMDT chamber** of ATLAS (2 multilayer with 58x4)
- Conduct simulations with Garfield ++
  - interpreting experimental measurements and for electronic development

## Importance:

- Gain experience with the gas mixture He/iC<sub>4</sub>H<sub>10</sub> (90/10)
- Tune the simulation program Garfield ++ due to weaknesses:
  - Simulate ionization process (number of primary electrons)
  - Predict the transport of electrons in Helium gas
    - hard to have a reliable prediction of the gas gain

# Helium-isobutane studies – Diethorn formula

- From experimental data analysis we receive an efficiency vs voltage curve
- Since the gas gain prediction of Garfield++ is limited, we set the gain as input parameter
  - receive an efficiency vs (gas) gain curve
- For comparison and tuning we need to convert gain into voltage which is possible via the

Diethorn formula:

$$G = \left[ \frac{E(r_{min})}{E_{min}(Q_0) Q_{gas}} \right]^{\frac{r_{min} E(r_{min}) \ln(2)}{\Delta V}}$$

$E(r_{min})$                       Electric field at wire  
 $Q_{gas}$                               pressure of used gas

Diethorn parameter	He/iC4H10 (90/10)
$E_{min}(Q_0)$	$32.4 \pm 2.98 \frac{V}{cm Torr}$
$\Delta V$	$26.01 \pm 0.53 V$

# Helium-isobutane studies – efficiency curve

## Experimental efficiency curve (x):

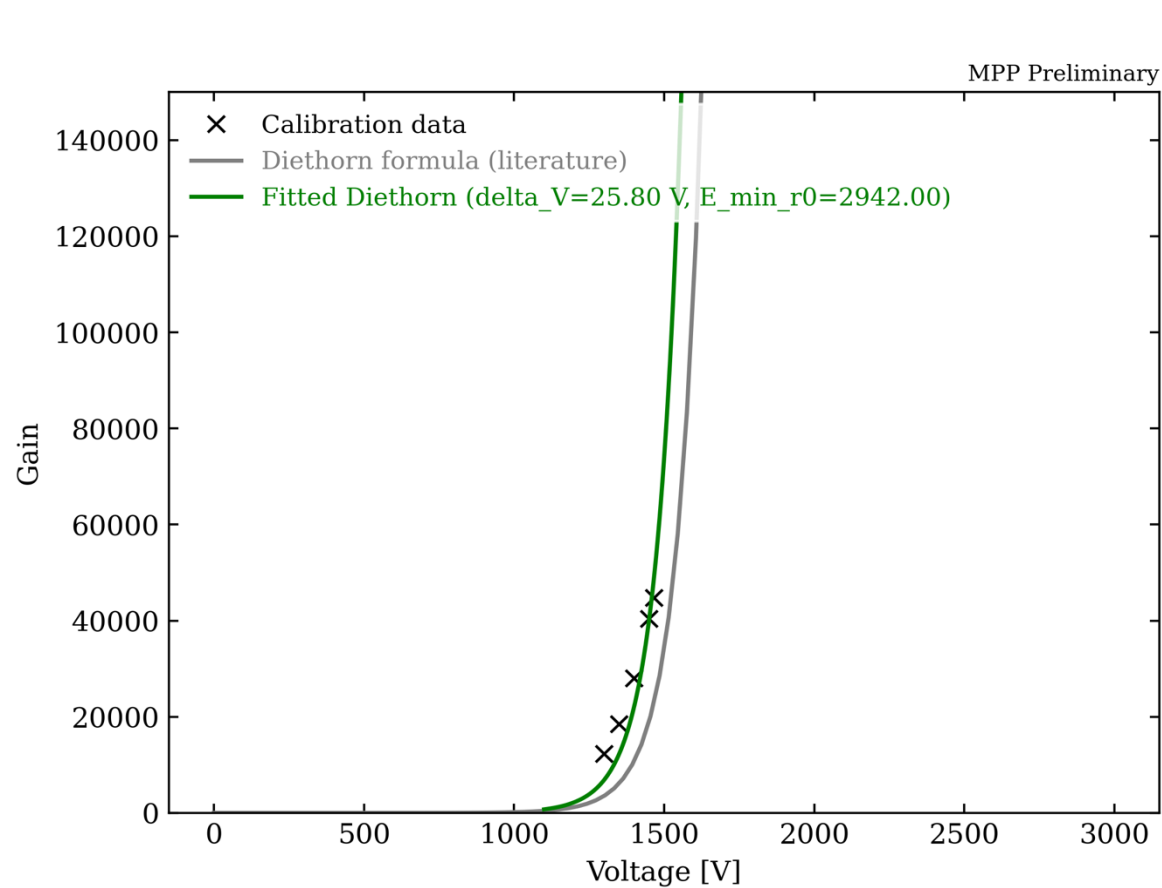

- Set one multilayer to the operating voltage of 1624V
- Vary the voltage of the other multilayer
- Trigger on cosmic rays
- Require at least 4 hits in multilayer at operating voltage

## Observation:

- Within the uncertainties of the simulation data the agreement is acceptable
- It would be better to tune the conversion for good matching of experiment and simulation

# Helium-isobutane studies – efficiency curve

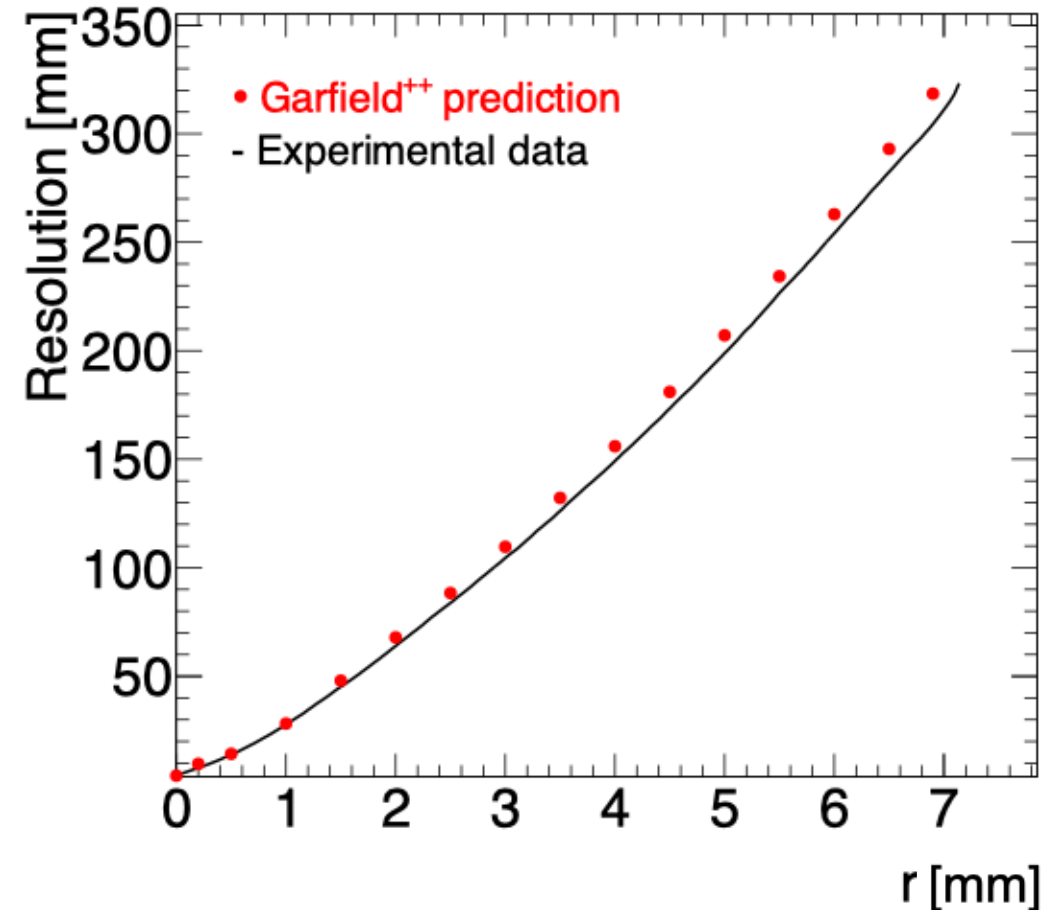

Fit of the Diethorn formula within the uncertainties of the parameters fits the data well and provides a suitable conversion of Gain to Voltage for our experimental purposes

# Helium-isobutane studies – rt relation

- rt relation of experimental (black) and simulation (red) data (same dataset of cosmic rays as before)
- Overall good agreement:
  - Maximum drift time of  $\sim 300$  ns in both data sets
  - Drift velocity in experiment is slightly higher than predicted by the simulation

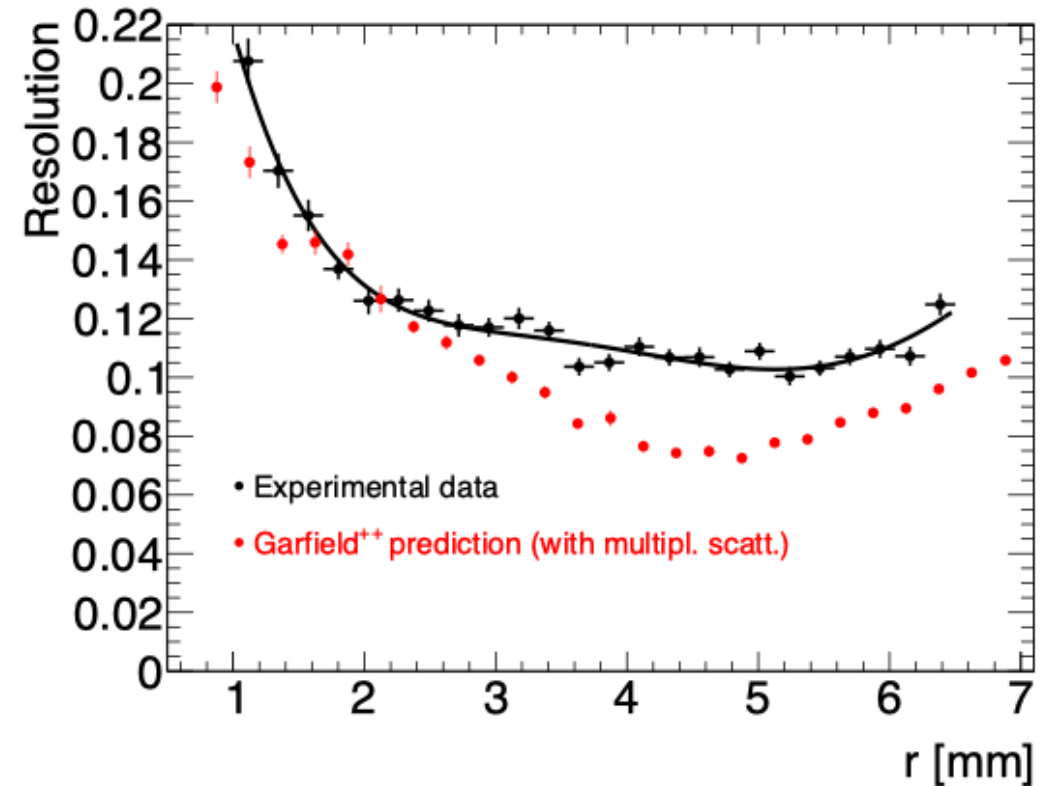

# Helium-isobutane studies - resolution

- Spatial resolution of simulation better than in the experiment
- Difference in resolution results from:
  - The difference in drift velocity impacts the resolution which explains the difference partly
  - Study multiple scattering correction
    - Here it was taken from GEANT4
    - Long experimental run with lead absorber

Cosmic rays  
He/iC<sub>4</sub>H<sub>10</sub> (90/10)  
50 mbar overpressure

# Summary

## Motivation of inner detector concept for FCCee:

- precision measurements of the Higgs boson → need of an excellent momentum resolution
- combine silicon and gaseous detectors
- advantageous to provide particle identification capabilities

## Straw tubes as possible implementation

- Compatible with drift chamber
- Provides advantages such as being an independent detector unit

## Producing a Straw tube chamber prototype at MPP

- Characterize complete prototype using the test beam in July at CERN

Tune Garfield++ → get reliable simulation predictions for our purposes

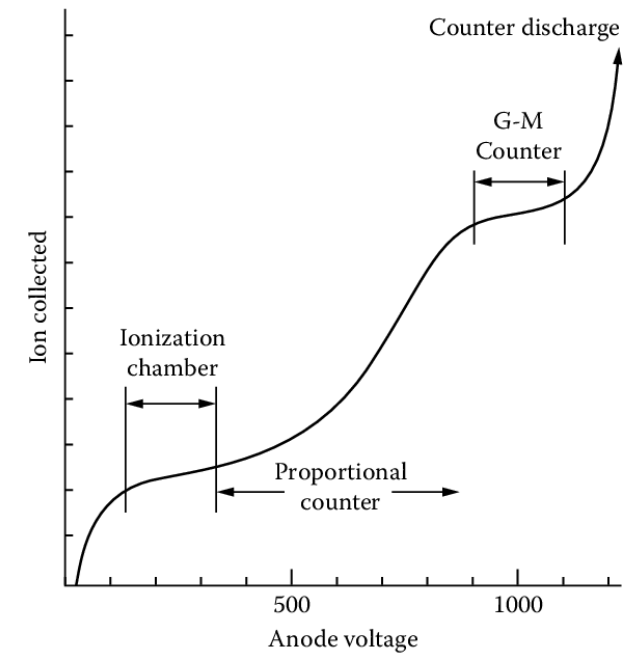

# Backup

# Gaseous Drift tube

- Detector Volume filled with gas (noble + quencher)
- Particle ionizes gas
- Apply voltage
  - Depending on the strength, the chamber is operated in different modes e.g.:
    - Ionization chamber
    - Proportional counter

# Momentum resolution

- The momentum resolution is composed of two components
  1. Position resolution

$$\frac{\sigma_p}{p} = \frac{2p}{Bq} \frac{1}{L^2} \sqrt{\frac{5}{N}} \sigma$$

2. Multiple scattering contribution

$$\frac{\sigma_p}{p} = \frac{13.6 \text{ MeV}}{qcBL} \sqrt{\frac{Nd}{X_0}}$$

## Nomenclature

$p$	particle momentum
$q$	charge of particle
$B$	magnetic field
$L$	length of the particle trajectory
$N$	number of measurement layers
$\sigma$	average spatial resolution
$\frac{Nd}{X_0}$	amount of detector material

# Resolution contributions (CLD, IDEA, Allegro)

Concept	Material	Position resolution	Multiple scattering resolution	Momentum resolution
CLD	7.5 %	0.06 %	0.31%	0.32 %
IDEA	4 %	0.13 %	0.23 %	0.26 %
Straws	4.5 %	0.13 %	0.24 %	0.27 %

# Simulation of the inner detector

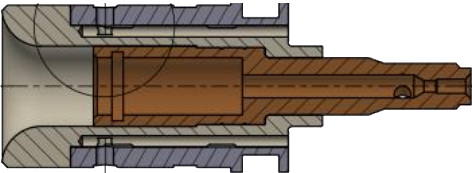

- Preliminary study of a straw tracker for gaseous volume
- 100 straw layers with increasing tube diameters from 10 mm to 15 mm with increasing distance from the beamline

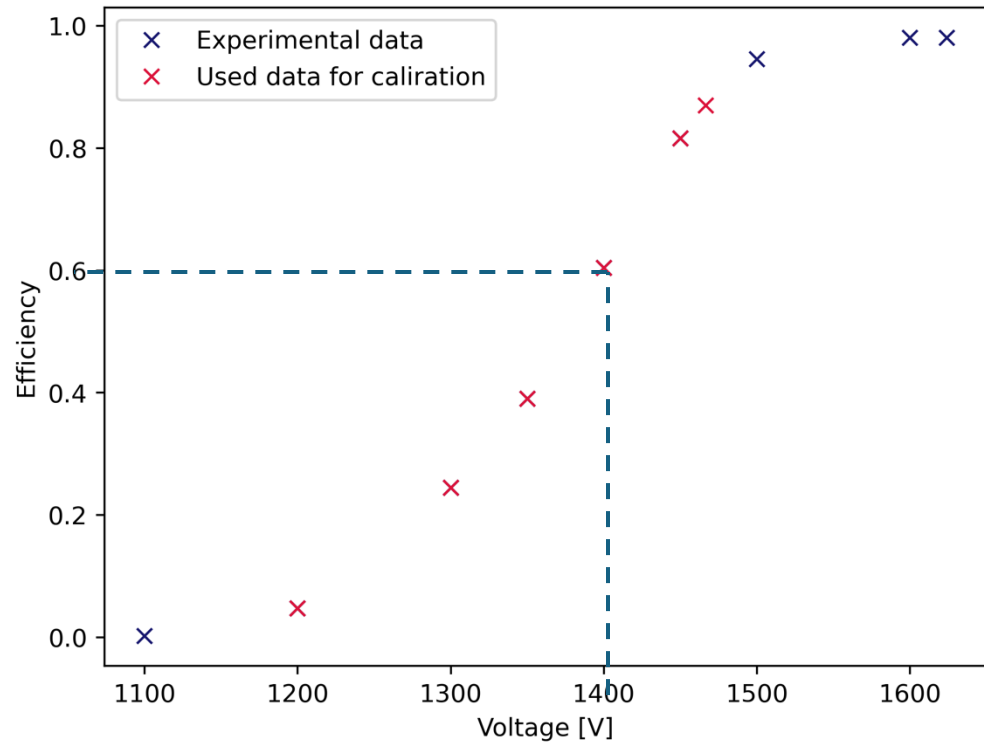

# Straw Tube production - tests

Tests conducted	Results
<p><b>Gas leakage test</b></p> <p><u>Operating conditions</u> Ar/CO<sub>2</sub> (93/7) at a pressure of <math>p = 1100</math> mbar</p>	No leaks detected by sniffing Argon
<p><b>Resistivity</b></p> <p>Measurement with digital voltmeter to check if the electrical glueing was successful</p>	✓
<p><b>Endplug leakage</b></p> <p><u>Operating conditions</u> Air at Atmospheric pressure</p> 	<p>Goal: current below 100 pA</p> <p>Result: tested until 2.8 kV → within the limit</p>
<p><b>Dark current</b></p> <p><u>Operating conditions</u> Ar/CO<sub>2</sub> (93/7) at a pressure of <math>p = 1100</math> mbar</p>	<p>Goal: current below 2 nA</p> <p>Result: tested up to 2.73 kV which corresponds to a gas gain of 380.000.000 → within the limit</p>

# Calibration of diethorn formula

For example:

- Write out voltage at a specific efficiency (exp data)
- Check what the gain value of this efficiency corresponds to in the simulation

# dE/dx measurement

- Beside a good momentum measurement, one wants to perform particle identification
- Standard procedure via calculating energy loss vs momentum
- Problem: energy loss follows a landau distribution
  - Caused by delta electrons (highly energetic, rare)
  - Impression of increased energy loss
  - Misinterpretation for particle identification

# dN/dx measurement

- Counting ionizations (= peak) along the track
- Delta electrons minor influence → Poisson distribution
- Particle separation capabilities enhanced by a factor of 2
  
- BUT: the standard gas mixture Ar/CO<sub>2</sub> won't work
- Ionization energy Argon: 15,8 eV
- USE: He/iC<sub>4</sub>H<sub>10</sub>
- Ionization energy Helium: 24,6 eV
- Less ionization clusters
- More separation in time
