Deconfinement and Equation of State in QCD

Péter Petreczky

What is deconfinement in QCD? What is the nature of the deconfined matter?

Tools: screening of color charges, EoS, fluctuation of conserved quantum numbers

QGP: state of strongly interacting matter for weakly interacting gas of quark and gluons? $T \gg \Lambda_{QCD}, g \ll 1$

Perturbative series is an expansion in $g$ and not $\alpha_s$

Loop expansion breaks down at some order

Problem: $g(\mu = 10^2 \text{GeV}) = \sqrt{4\pi \alpha_s(\mu = 10^2 \text{GeV})} \approx 1$

$g(\mu = 10^{16} \text{GeV}) \approx 1/2$

EFT approach: EQCD

Magnetic screening scale: non-perturnative

Lattice QCD
Lattice QCD calculations at $T>0$ around 2002:

\[ T_c \simeq 173\text{MeV} \]

for both chiral transition and deconfinement transition (in terms of Polyakov loop)

Problems:
\[
N_\tau = 4 : a = 1/(N_\tau a) = 1/(4T)
\]

\[
m_\pi = (500 - 800)\text{MeV}
\]

Continuum limit and physical masses are needed
\[
N_\tau \to \infty
\]
\[
m_\pi = 140\text{MeV}
\]

This task can be accomplished using improved staggered fermions actions:
Highly Improved Staggered Quark (HISQ)
Stout action

Fluctuations of conserved charges: new look into deconfinement and QGP properties
Renormalized chiral condensate introduced by Budapest-Wuppertal collaboration

\[ \langle \bar{\psi} \psi \rangle_q \Rightarrow \Delta_q^R(T) = m_s r_1^4 \left( \langle \bar{\psi} \psi \rangle_q,T - \langle \bar{\psi} \psi \rangle_q,T=0 \right) + d, \quad q = l, s \]

With choice: \( d = \langle \bar{\psi} \psi \rangle^{T=0}_{m_q=0} \)

Borsanyi et al, JHEP 1009 (2010) 073

- after extrapolation to the continuum limit and physical quark mass HISQ/tree calculation agree with stout results \( T_c = (154 \pm 8 \pm 1\text{(scale)})\text{MeV} \)

- strange quark condensate does not show a rapid change at the chiral crossover => strange quark do not play a role in the chiral transition
Deconfinement and color screening

Onset of color screening is described by Polyakov loop (order parameter in SU(N) gauge theory)

\[ L = \text{tr} \mathcal{P} e^{ig \int_0^{1/T} d\tau A_0(\tau, \vec{x})} \]

\[ \exp(-F_{Q\bar{Q}}(r, T)/T) = \frac{1}{9} \langle \text{tr} L(r) \text{tr} L^\dagger(0) \rangle \]

\[ F_{Q\bar{Q}}(r \to \infty, T) = 2F_Q(T) \]

\[ L_{\text{ren}} = \exp(-F_Q(T)/T) \]

2+1 flavor QCD, continuum extrapolated (work in progress with Bazavov, Weber …)

Similar results with stout action  Borsanyi et al, JHEP04(2015) 138
Polyakov and gas of static-light hadrons

\[ Z_{Q\bar{Q}}(T)/Z(T) = \sum_n \exp(-E_n^{Q\bar{Q}}(r \to \infty)/T) \]

Energies of static-light mesons:

\[ E_n^{Q\bar{Q}}(r \to \infty) = M_n - m_Q \]

Free energy of an isolated static quark:

\[ F_Q(T) = -\frac{1}{2}(T \ln Z_{Q\bar{Q}}(T) - T \ln Z(T)) \]

Megias, Arriola, Salcedo, PRL 109 (12) 151601

Bazavov, PP, PRD 87 (2013) 094505

Ground state and first excited states are from lattice QCD
Michael, Shindler, Wagner, arXiv1004.4235
Wagner, Wiese, JHEP 1107 016, 2011

Higher excited state energies are estimated from potential model
Gas of static-light mesons only works for \( T < 145 \) MeV
The entropy of static quark

\[ S_Q = -\frac{\partial F_Q}{\partial T} \]

At low temperature \( T \) the entropy \( S_Q \) increases reflecting the increase of states the heavy quark can be coupled to.

At high temperature the static quark only “sees” the medium within a Debye radius, as \( T \) increases the Debye radius decreases and \( S_Q \) also decreases.

The onset of screening corresponds to peak is \( S_Q \) and its position coincides with \( T_c \).
Casimir scaling of the Polyakov loop

Instead of fundamental representations consider Polyakov loop $P_n$ in arbitrary representation $n$

$$P_3 = L_{ren}$$

Casimir scaling: free energy is proportional to quadratic Casimir operator $C_n$ of rep $n$

$$R_n = C_n/C_3$$

Expected in weak coupling expansion: e.g. at LO

$$F_Q^n = -C_n \alpha_s m_D$$
Casimir scaling of the Polyakov loop (con’t)

\[ \delta_n = 1 - \frac{P_n^{1/R_n}}{P_3} \]

Casimir scaling holds for \( T>300 \) MeV

color screening like in weakly coupled QGP?
Equation of state in the continuum limit

Equation of state has been calculated in the continuum limit up to $T=400$ MeV using two different quark actions and the results agree well.

Bazavov et al, PRD 90 (2014) 094503

**Hadron resonance gas (HRG):**

Interacting gas of hadrons = non-interacting gas of hadrons and hadron resonances (virial expansion, Prakash & Venugopalan)

HRG agrees with the lattice for $T < 145$ MeV

$$T_c = (154 \pm 9)\text{MeV}$$

$$\epsilon_c \simeq 300\text{MeV/fm}^3$$

$$\epsilon_{low} \simeq 180\text{MeV/fm}^3 \leftrightarrow \epsilon_{nucl} \simeq 150\text{MeV/fm}^3$$

$$\epsilon_{high} \simeq 500\text{MeV/fm}^3 \leftrightarrow \epsilon_{proton} \simeq 450\text{MeV/fm}^3$$
How Equation of state changed since 2002

- Much smoother transition to QGP
- The energy density keeps increasing up to 450 MeV instead of flattening
The high temperature behavior of the trace anomaly is not inconsistent with weak coupling calculations (EQCD) for $T > 300$ MeV.

For the entropy density the continuum lattice results are below the weak coupling calculations for $T < 500$ MeV.

At what temperature can one see good agreement between the lattice and the weak coupling results?
QCD thermodynamics at non-zero chemical potential

Taylor expansion:

\[ p(T, \mu_B, \mu_Q, \mu_S) \frac{1}{T^4} = \sum_{i,j,k} \chi_{ijk} BQS \cdot \left( \frac{\mu_B}{T} \right)^i \left( \frac{\mu_Q}{T} \right)^j \left( \frac{\mu_S}{T} \right)^k \]

\[ p(T, \mu_u, \mu_d, \mu_s) \frac{1}{T^4} = \sum_{i,j,k} \chi_{ijk} \cdot \left( \frac{\mu_u}{T} \right)^i \left( \frac{\mu_d}{T} \right)^j \left( \frac{\mu_s}{T} \right)^k \]

\[ \chi^{abc}_{ijk} = T^{i+j+k} \frac{\partial^i}{\partial \mu_a^i} \frac{\partial^j}{\partial \mu_b^j} \frac{\partial^k}{\partial \mu_c^k} \frac{1}{VT^3} \ln Z(T, V, \mu_a, \mu_b, \mu_c) \bigg|_{\mu_a=\mu_b=\mu_c=0} \]

Taylor expansion coefficients give the fluctuations and correlations of conserved charges, e.g.

\[ \chi_2^X = \chi_X = \frac{1}{VT^3} (\langle X^2 \rangle - \langle X \rangle^2) \]

\[ \chi_{11}^{XY} = \frac{1}{VT^3} (\langle XY \rangle - \langle X \rangle \langle Y \rangle) \]

information about carriers of the conserved charges (hadrons or quarks)

probes of deconfinement
Equation of state at non-zero baryon density

Taylor expansion up to 4\textsuperscript{th} order for net zero strangeness $n_S = 0$ and $r = n_Q/n_B = Z/A = 0.4$

Moderate effects due to non-zero baryon density up to $\mu_B/T = 2 \leftrightarrow \sqrt{s} \sim 20\text{GeV}$

Energy density at freeze-out is independent of $\mu_B$
Deconfinement: fluctuations of conserved charges

\[ \chi_B = \frac{1}{VT^3} \left( \langle B^2 \rangle - \langle B \rangle^2 \right) \]

baryon number

\[ \chi_Q = \frac{1}{VT^3} \left( \langle Q^2 \rangle - \langle Q \rangle^2 \right) \]

electric charge

\[ \chi_S = \frac{1}{VT^3} \left( \langle S^2 \rangle - \langle S \rangle^2 \right) \]

strangeness

Ideal gas of massless quarks:

\[ \chi_B^{SB} = \frac{1}{3} \quad \chi_Q^{SB} = \frac{2}{3} \quad \chi_S^{SB} = 1 \]

conserved charges carried by light quarks

filled: HISQ, \( N_t = 6, 8 \)

open: stout continuum

HotQCD: PRD86 (2012) 034509

Deconfinement of strangeness

Partial pressure of strange hadrons in uncorrelated hadron gas:

\[ P_S = \frac{p(T) - p_{S=0}(T)}{T^4} = M(T) \cosh\left(\frac{\mu_S}{T}\right) + \]

\[ B_{S=1}(T) \cosh\left(\frac{\mu_B - \mu_S}{T}\right) + B_{S=2}(T) \cosh\left(\frac{\mu_B - 2\mu_S}{T}\right) + B_{S=3}(T) \cosh\left(\frac{\mu_B - 3\mu_S}{T}\right) \]

\( v_1 = \chi^{BS}_{31} - \chi^{BS}_{11} \)

\( v_2 = \frac{1}{3} (\chi^S_4 - \chi^S_2) - 2\chi^{BS}_{13} - 4\chi^{BS}_{22} - 2\chi^{BS}_{31} \)

should vanish!

- \( v_1 \) and \( v_2 \) do vanish within errors at low \( T \)
- \( v_1 \) and \( v_2 \) rapidly increase above the transition region, eventually reaching non-interacting quark gas values

Bazavov et al, PRL 111 (2013) 082301
At high temperatures quark number fluctuations can be described by weak coupling approach due to asymptotic freedom of QCD.

- Lattice results converge as the continuum limit is approached.
- Good agreement between lattice and the weak coupling approach for 2\textsuperscript{nd} and 4\textsuperscript{th} order quark number fluctuations as well as for correlations.

What about charm hadrons?

\[ \chi_{XYC}^{Xnm} = T^{m+n+l} \frac{\partial^{n+m+l} p(T, \mu_X, \mu_Y, \mu_C)}{\partial \mu_X^n \partial \mu_Y^m \partial \mu_C^l} / T^4 \]

\[ m_c \gg T \quad \text{only } |C|=1 \text{ sector contributes} \]

In the hadronic phase all BC-correlations are the same!

Hadronic description breaks down just above \( T_c \)

\[ \Rightarrow \text{open charm deconfines above } T_c \]

The charm baryon spectrum is not well known (only few states in PDG), HRG works only if the “missing” states are included.
Quasi-particle model for charm degrees of freedom

Charm dof are good quasi-particles at all $T$ because $M_c >> T$ and Boltzmann approximation holds

$$p^C(T, \mu_B, \mu_c) = p^C_q(T) \cosh(\mu_C + \mu_B/3) + p^C_B(T) \cosh(\mu_C + \mu_B) + p^C_M(T) \cosh(\mu_C)$$

$$\chi^C_2, \chi^{BC}_{13}, \chi^{BC}_{22} \Rightarrow p^C_q(T), p^C_M(T), p^C_B(T)$$

$$\hat{\mu}_X = \mu_X / T$$

Partial meson and baryon pressures described by HRG at $T_c$, and dominate the charm pressure then drop gradually, charm quark only dominant dof at $T > 200$ MeV

Partial pressures drop because hadronic excitations become broad at high temperatures (bound state peaks merge with the continuum)

Vice versa for quarks

Mukherjee, PP, Sharma, arXiv:1509.08887
Summary

• The deconfinement transition temperature defined in terms of the free energy of static quark agrees with the chiral transition temperature for physical quark mass.

• Equation of state are known in the continuum limit up to $T=400$ MeV at zero baryon density and the effect of non vanishing baryon densities seem to be moderate.

• Hadron resonance gas (HRG) can describe various thermodynamic quantities at low temperatures.

• Deconfinement transition can be studied in terms of fluctuations and correlations of conserved charges, it manifest itself as a abrupt breakdown of hadronic description that occurs around the chiral transition temperature.

• Charm hadrons can exist above $T_c$ and are dominant dof for $T<180$ MeV.

• For $T > (300-400)$ MeV weak coupling expansion works well for certain quantities (e.g. quark number susceptibilities), more work is needed to establish the connection between the lattice and the weak coupling results.

• Comparison of lattice and HRG results for certain charm correlations hints for existence of yet undiscovered excited baryons.
Domain wall Fermions and $U_A(1)$ symmetry restoration

Domain Wall Fermions, Bazavov et al (HotQCD), PRD86 (2012) 094503

\[ \chi_i = \int d^4 x G_i(x) \]

\[ \chi_{\pi} = \chi_{\delta} + \chi_{\text{disc}} \]
\[ \chi_{\delta} = \chi_{\pi} - \chi_{5,\text{disc}} \]
\[ \chi_{\text{disc}} = \chi_{5,\text{disc}} \]
\[ \chi_{\text{disc}} = -\chi_{5,\text{disc}} \]
