

# What to learn from test beams for PXD simulation and clustering?

F2F Meeting Prague 2014

B. Schwenker

For the test beam crew

# A first approach to answer ...

- Local PXD simulation relies on well working DEPFET and ASICS (DCD/DHP):
  - All pixel drain current  $I_d$  in dynamic range
    - After dynamic 2bit current correction
    - Dynamic range of DCD:  $\sim 24\mu\text{A}$
    - Signal current ( $\sim 2\mu\text{A}$ ) && baseline current ( $\sim 60\mu\text{A}$ ) && pedestals (??)
  - Global gain for all pixels:  $g \sim 500\text{pA/e}$
  - El. noise (DCD/DHP): 100-200e
  - 8bit ADC channels in DCD
    - Linear transfer curve at full speed
    - Least significant bit  $\sim 200\text{e}$

# A first approach to answer ...

- November 2014 test beam at CERN tells us whether this can work:
  - Are all channels working for long sensor with ASICS?
  - What are the calibration constants to compare data with simulation?
    - El. Noise,  $Gq$ , LSB?
  - Does our signal match with simulation?
    - Landau, residuals, cluster size

# The prototype detector

- Pixel pitch:  $50 \times 75 \mu\text{m}^2$
- Thickness: 50 $\mu\text{m}$  thick sensor
- 192 physical columns
- 480 physical rows

- Same detector as in January 2014
- 2 $\mu\text{m}$  pointing error from telescope  
→ in-pixel stat.
- 2bit pedestal subtraction (DCDB)  
→ Largest problem last time

- ASICS: DCDBv2, DHP02, SwitcherB1.8G
- Speed: 250MHz (nominal 320MHz)

# Local coordinate system

U; columns [0,192]

V, rows [0,480]

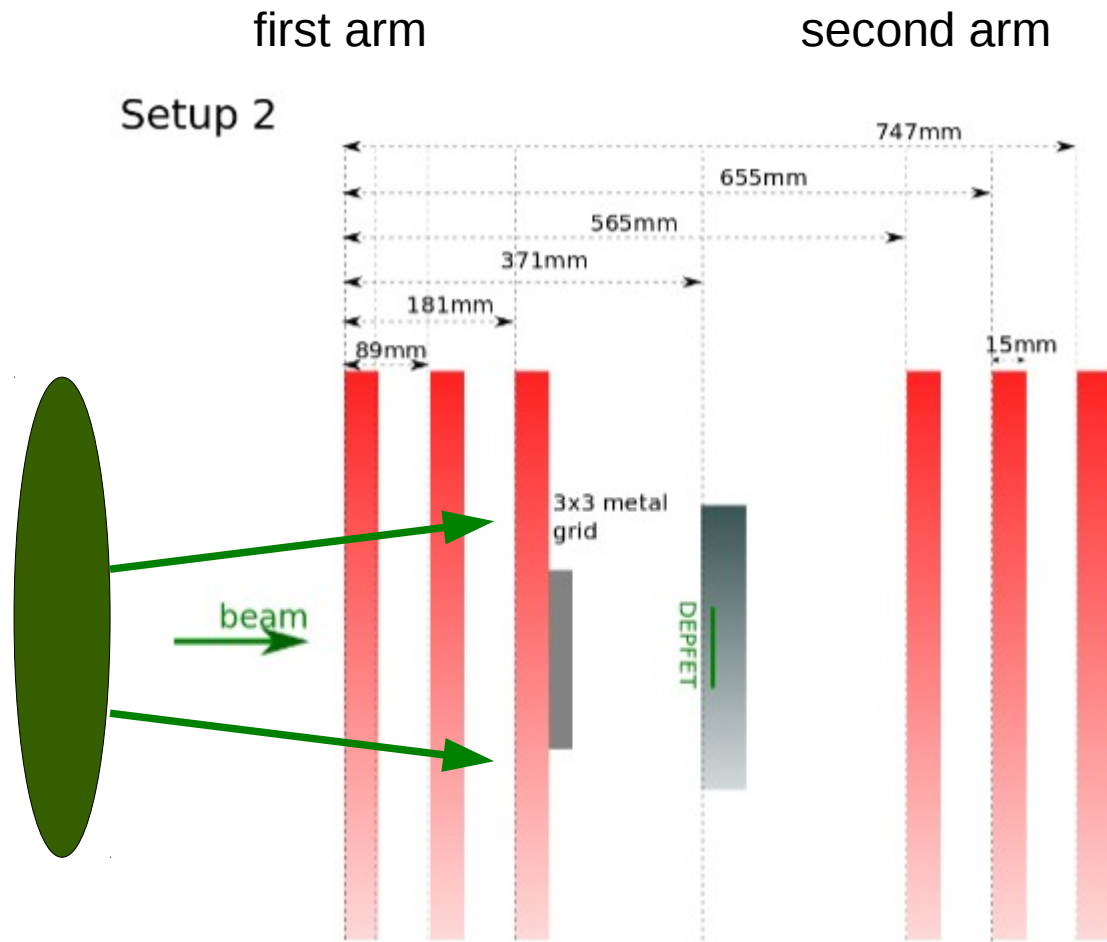

# Only one DCD/DHP readout

# Data sample from CERN

- Many short runs needed for debugging and not usable for validation.
- Runs at perpendicular incidence; 120GeV
  - Runs: 209, 210, 211, 212
  - First DCD/DHP pair used
  - Total of 350k tel. tracks with DEPFET hit
- Runs at 30° tilted sensor
  - Only one long run: Run325
  - Tilt around local horizontal (x) axis
  - Only few tracks (<10k matched tracks)

# EUDET Tracking

- 6 eudet layer,  $\sim 2\mu\text{m}$  error

- trigger PMT's before and after eudets

- triggered track: 6hit eudet hit(!)

- z axis is aligned to beam axis

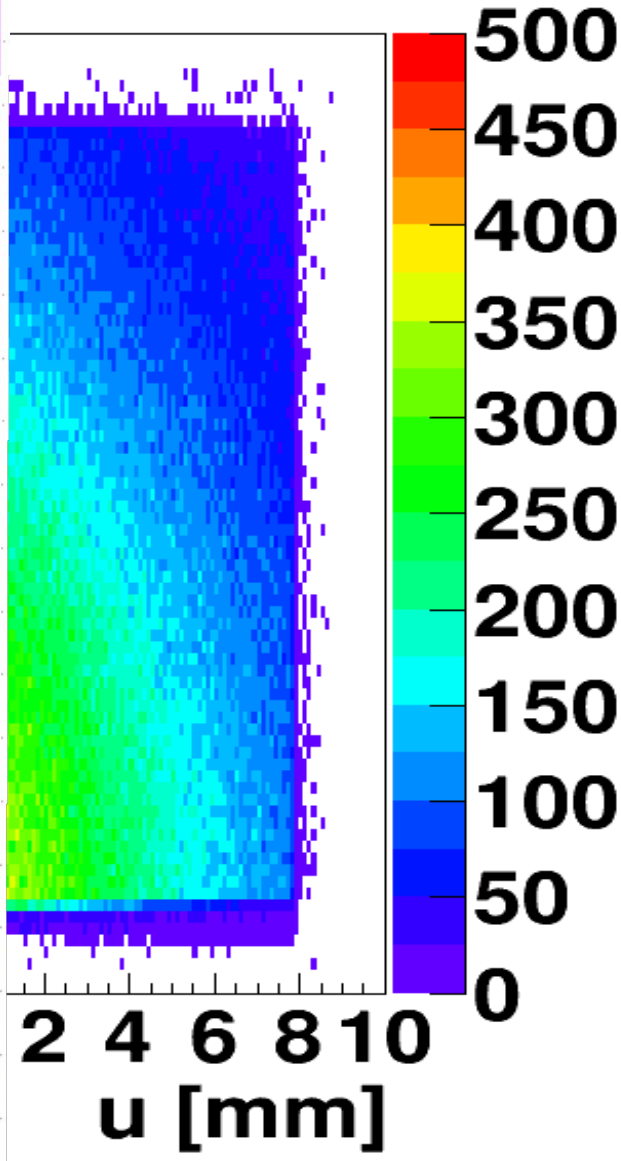

- finding/alignment/tracking in ILCSsoft.

# Beam Spot: Tel. Acceptance

**v [mm]**

**number of particles**

# DEPFET hits vs. tel. tracks

# DEPFET hits vs. tel. tracks

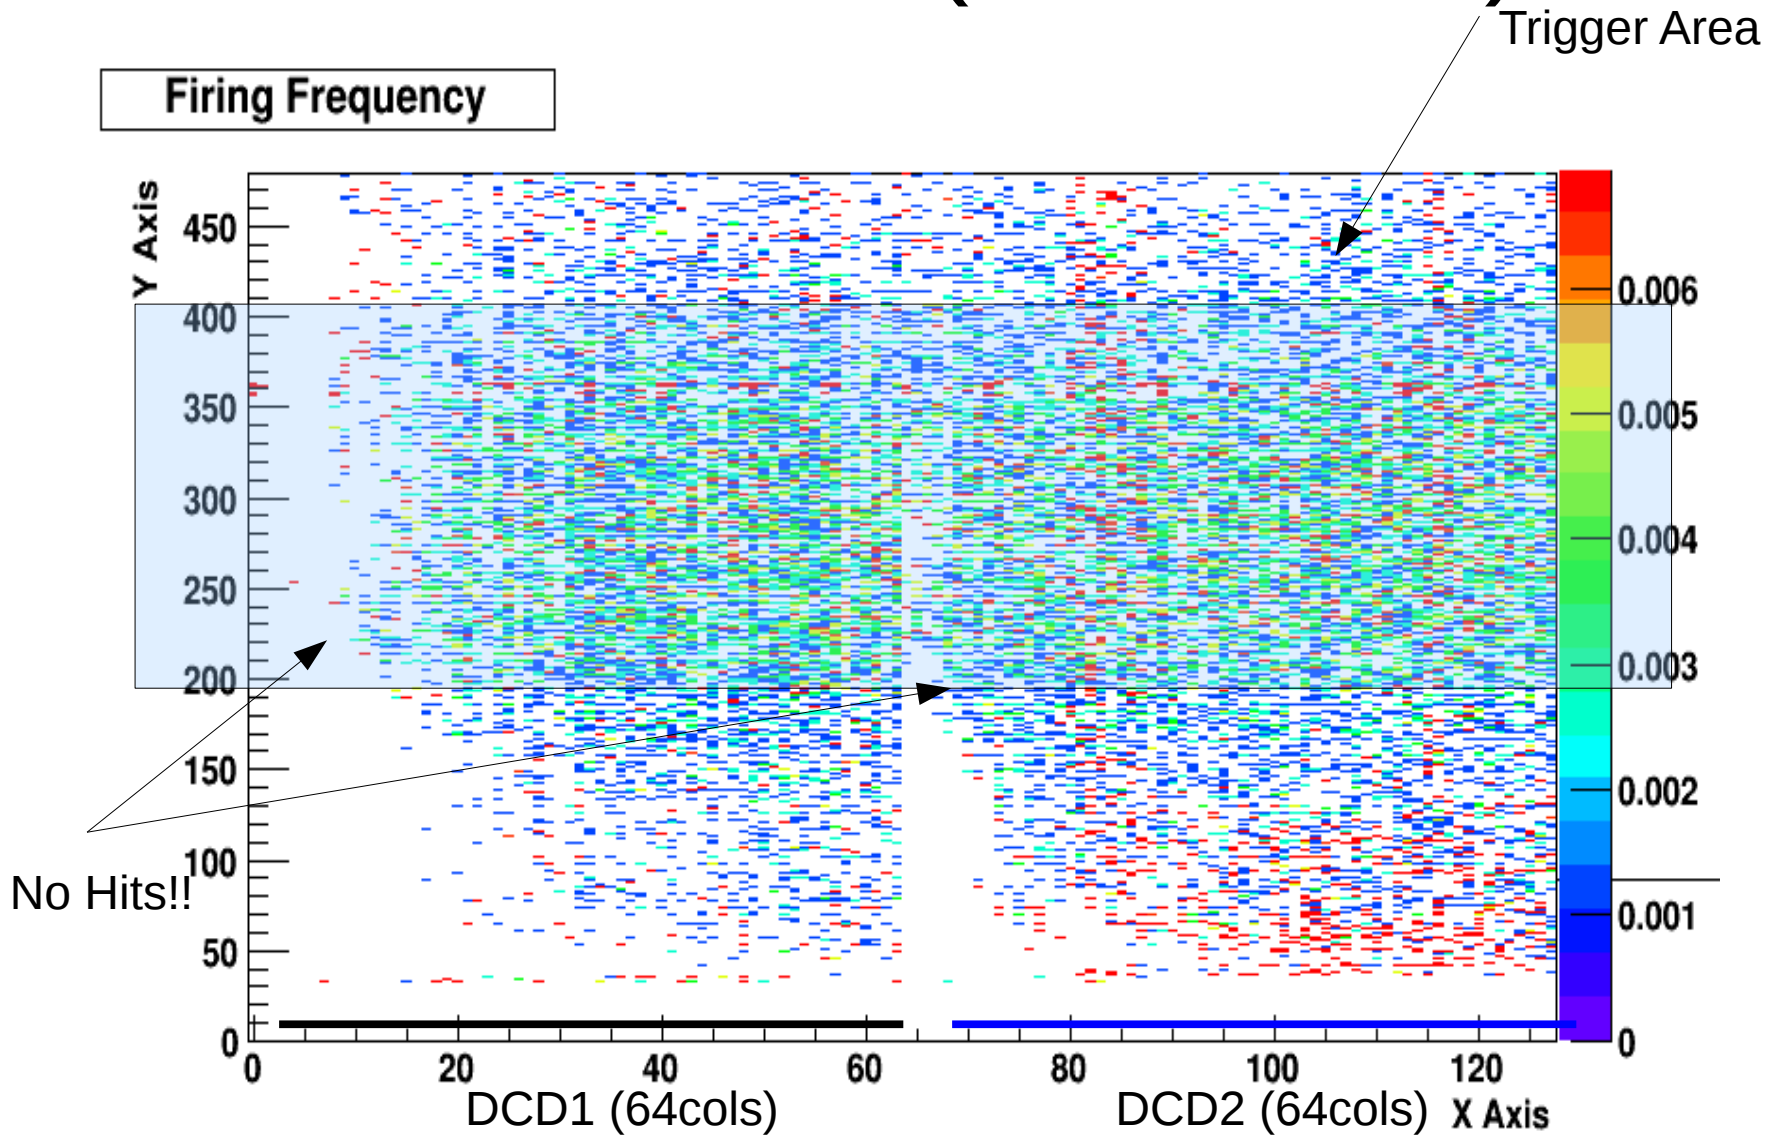

:- Tracks cross only  
rows 140-270

:- sizeable fraction of pixel  
which record no hits

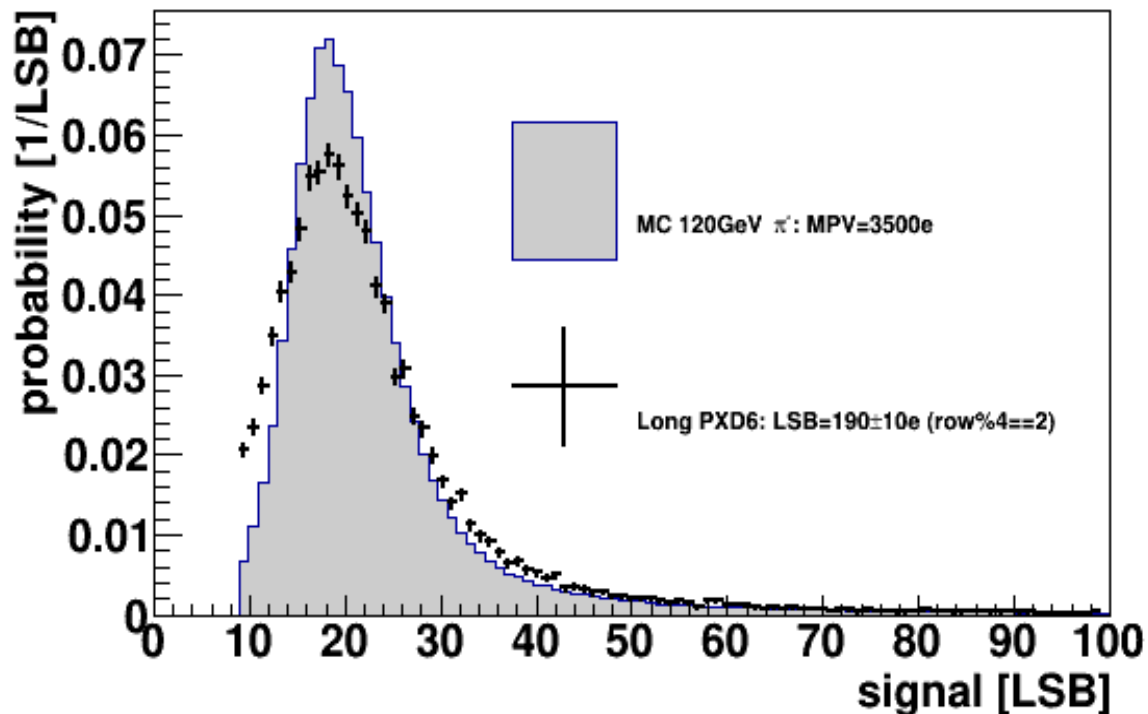

:- drain current out of dynamic  
range at DCD input  
(most likely explanation)

:- Variation of pedestals currents  
larger than expected from  
small sensor.

# Improvement from 2bit pedestal correction (Jan. 2014)

# Landau (50um Si)

MPV~20 LSB

- DEPFET hits matched to track.

→ clean hit sample

- LSB ~ 190 electrons

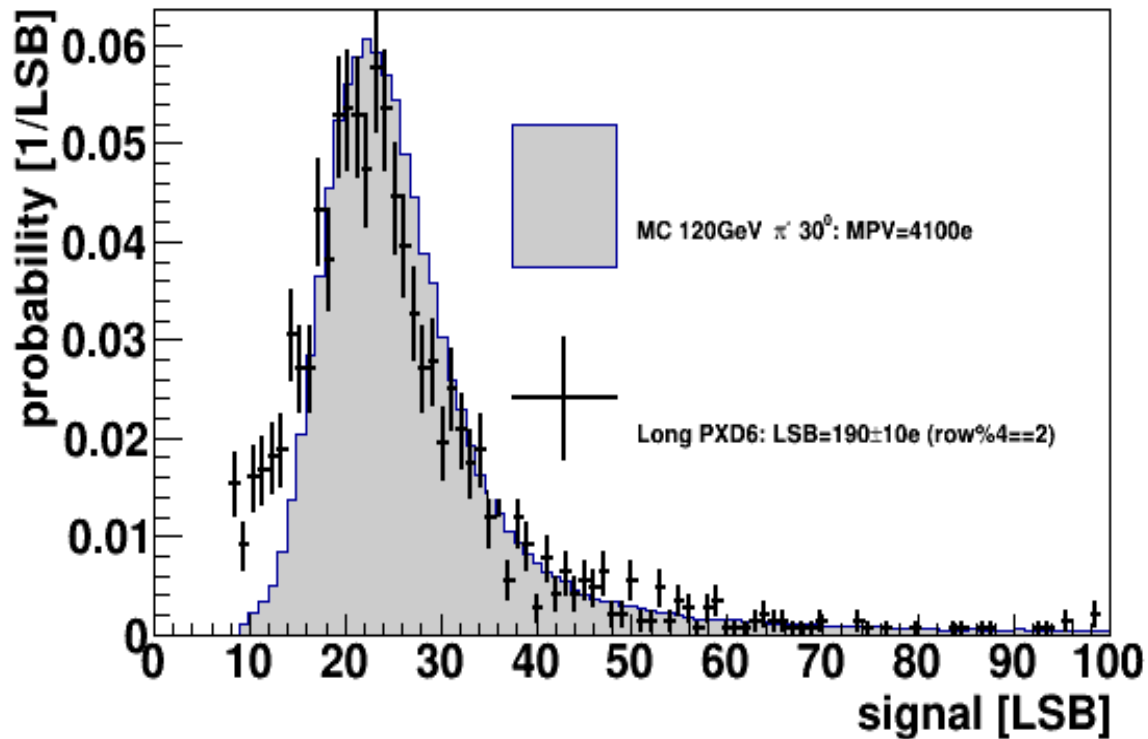

→ scaled to MC data (PXD digitizer)

- FWHM ~ 2000 electrons (Landau fluctuations)

→ fine spaced sampling of noise.

- Only use 4th row to avoid dead channels.

# Landau (50um Si; 30° tilt)

MPV~21 LSB

- DEPFET hits matched to track.

→ clean hit sample

- LSB ~ 190 electrons

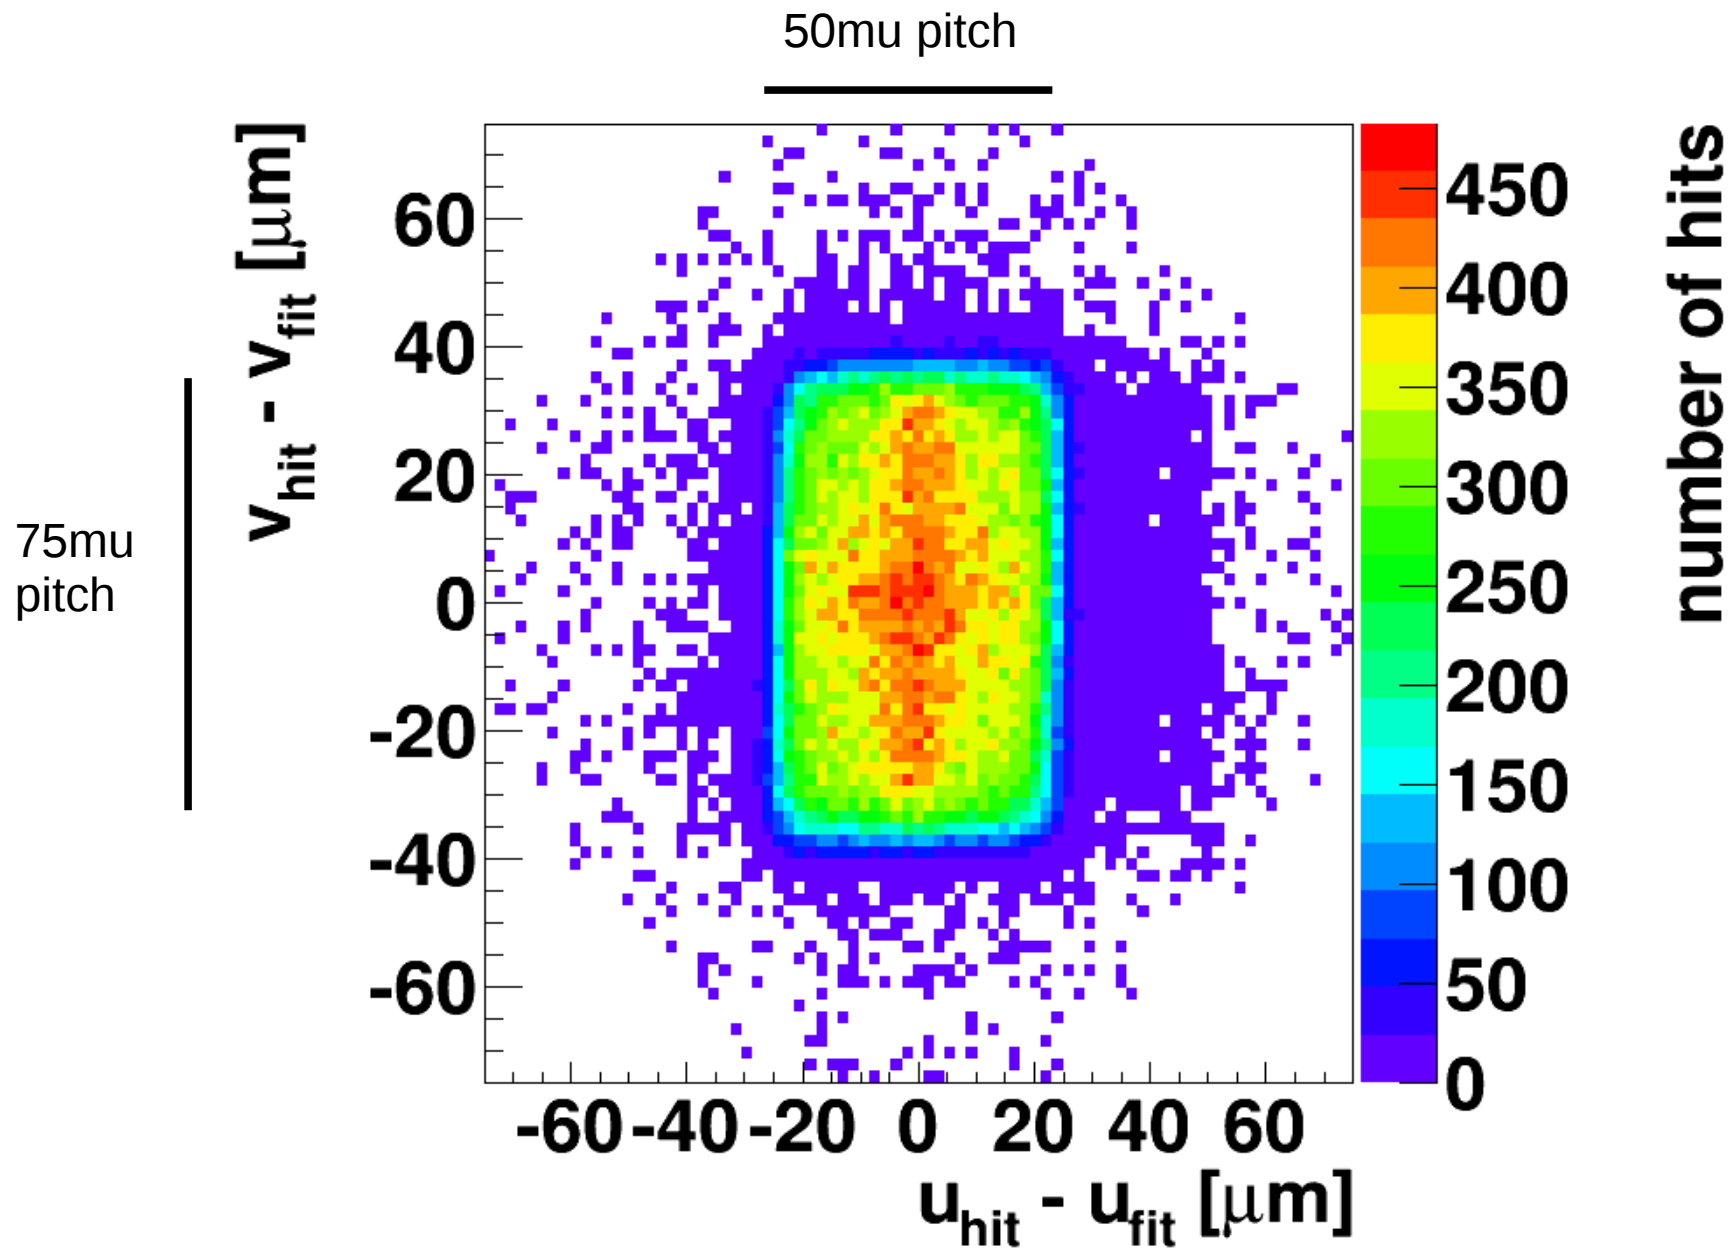

→ scaled to MC data (PXD digitizer)

- FWHM ~ 2000 electrons (Landau fluctuations)

→ fine spaced sampling of noise.

- Only use 4th row to avoid dead channels.

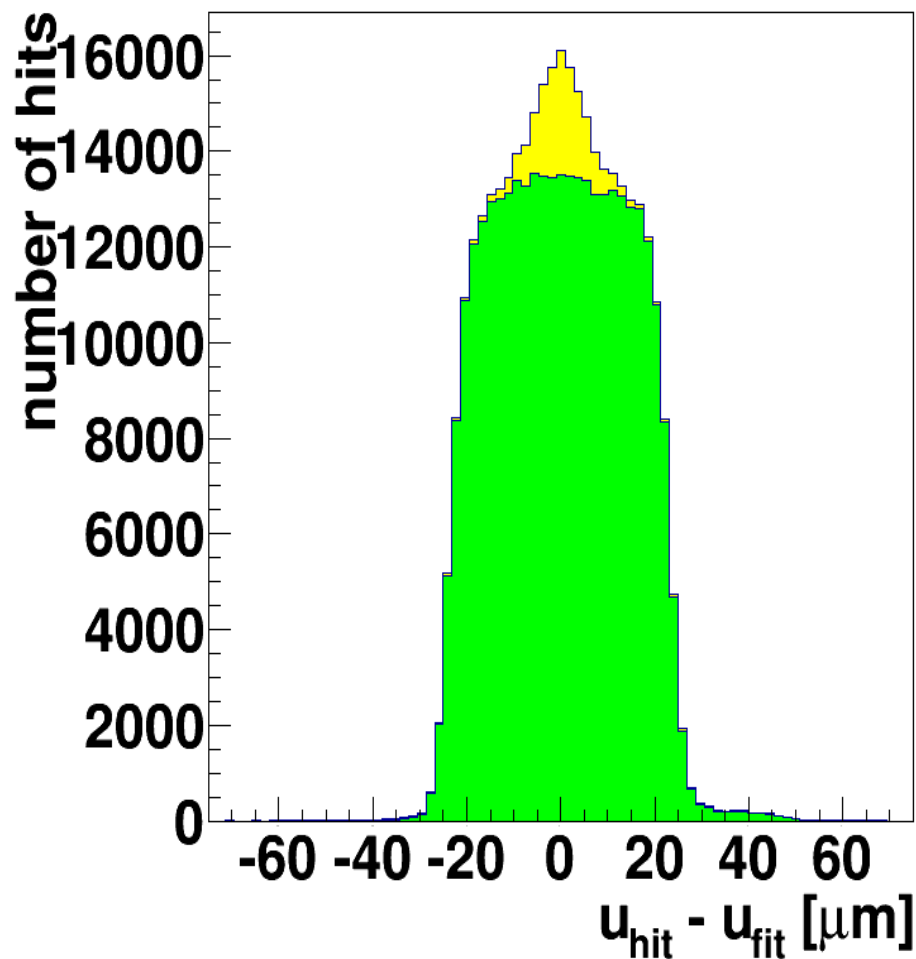

# 2D Residuals (perp. incidence)

# 1D residuals (perp. incidence)

Mostly 1px clusters, few two pixels when track hits pixel edge  
(having much better resolution)

# Summary

- 2bit pedestal subtraction is clear improvement compared to Jan. 2014
  - however not enough; still many dead pixels
  - Clear hardware topic
- We measure landaus, clusters and residuals as expected for high threshold operation.
  - Thresholds are  $8x\text{LSB} \sim 1500e$
  - Spatial resolution (to lesser extent: pxd hit effi) degrades significantly for such high thresholds.

Thanks

# Pedestals and Dynamic Range

- Same coordinates as before

- Zero pedestal: out of DCD range!!

- Pedestal variation too strong to operate all sensor

- There is also a row wise patten in Pedestals.

- Questions:

A) How much can 2bit pedestal dac help (not used in tb)?

B) How much of pedestal is due to Mechanic stress/ bad optimization?
