Evidence for Dark Matter

Evidence for the existence of an unseen, "dark", component in the energy density of the Universe comes from several independent observations at different length scales

COSMOLOGICAL OBSERVATIONS

• 'Local' matter density

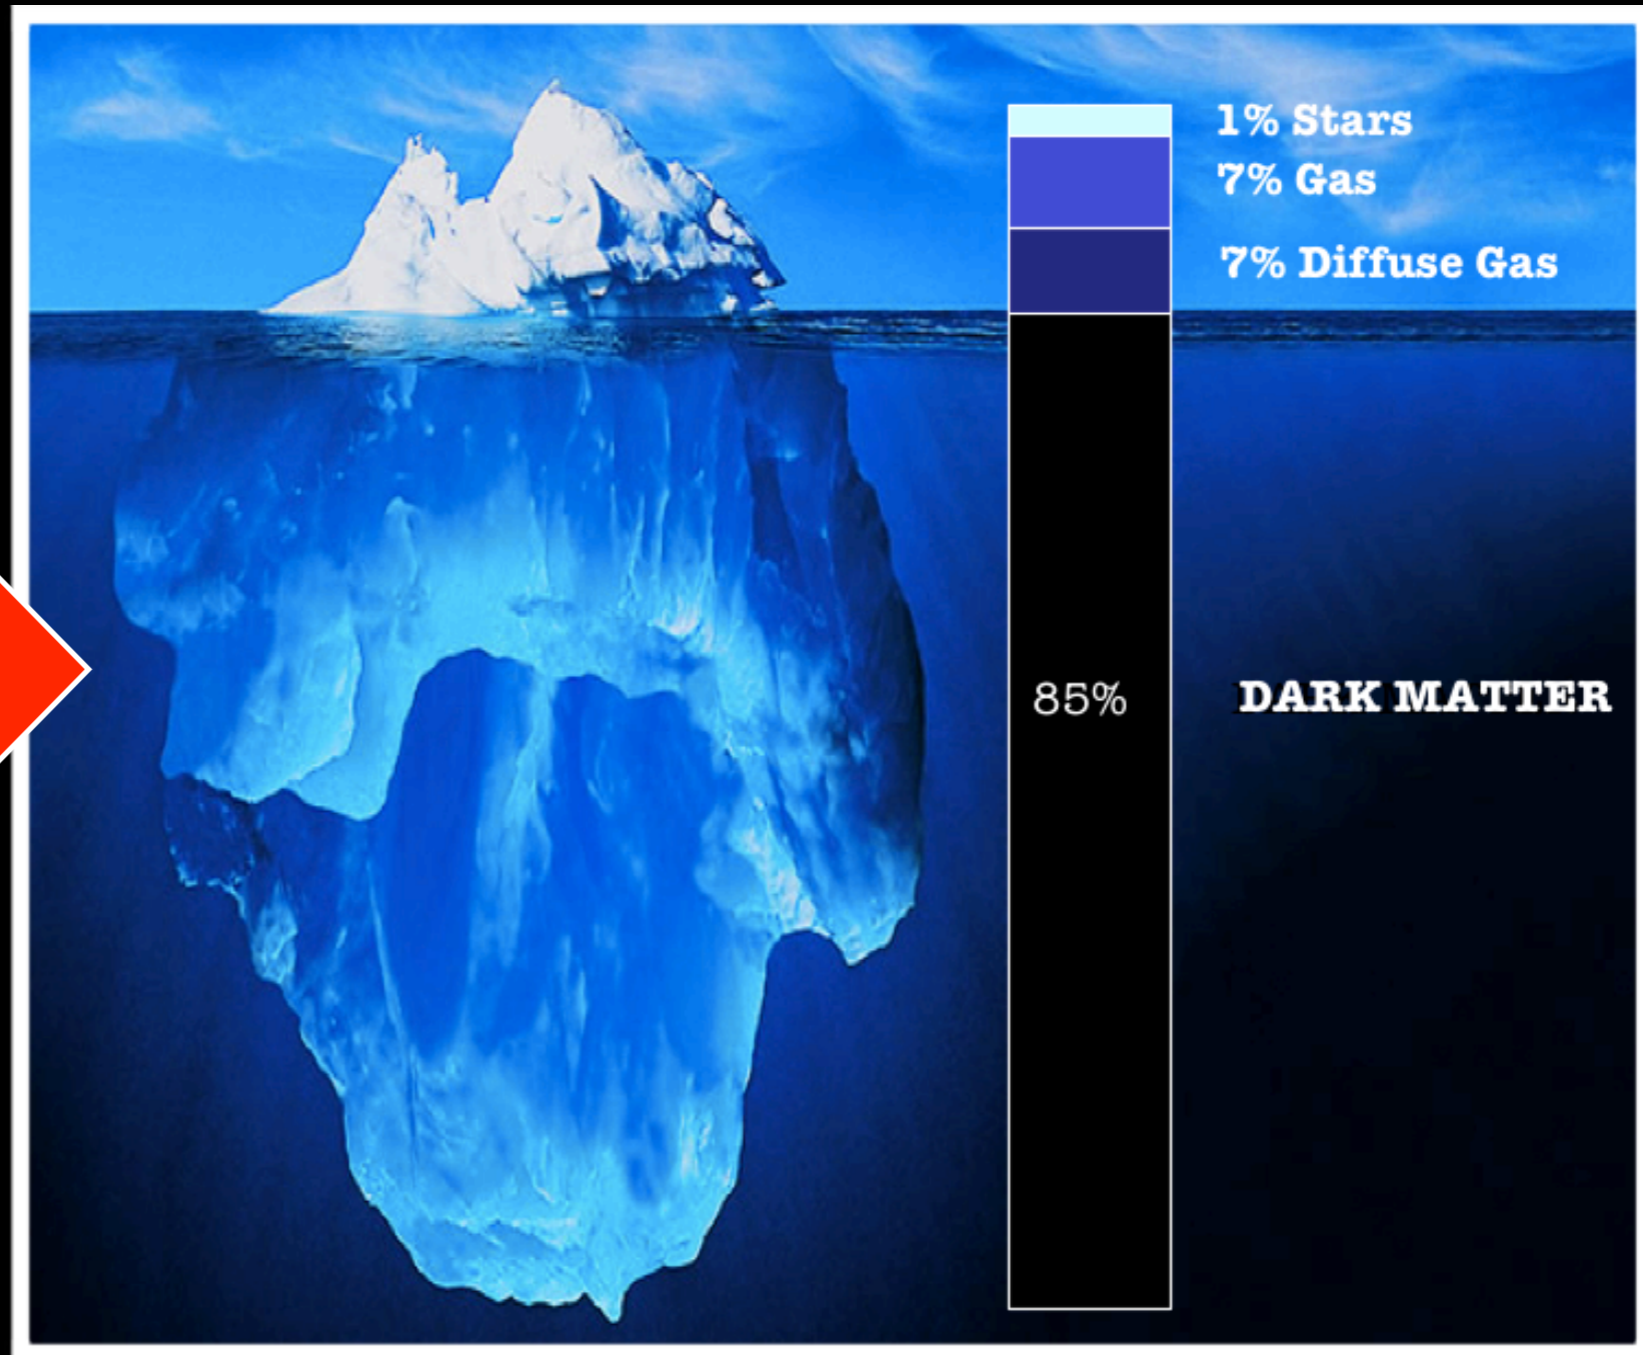

• Rotation Curves

• Clusters of galaxies

• CMB

What do we know?

An extraordinarily rich zoo of non-baryonic Dark Matter candidates! In order to be considered a viable DM candidate, a new particle has to pass the following 10-point test

1) Ωh^2 OK?

2) Is it cold?

3) Is it neutral?

4) Is BBN ok?

5) Stars OK?

What do we know?

An extraordinarily rich zoo of non-baryonic Dark Matter candidates! In order to be considered a viable DM candidate, a new particle has to pass the following 10-point test

1) Ωh^2 OK?

2) Is it cold?

3) Is it neutral?

4) Is BBN ok?

5) Stars OK?

6) Collisionless?

7) Couplings OK?

8) γ -rays OK?

9) Astro bounds?

10) Can probe it?

TAOSO, GB & MASIERO 2007

The DM candidates Zoo

WIMPs

Natural Candidates

Arising from theories addressing the stability of the electroweak scale etc.

- E.g. SUSY Neutralino

Ad-Hoc Candidates

Postulated to solve the DM Problem

- Minimal DM
- Maverick DM
- etc.

Other

- Axions

Postulated to solve the strong CP problem

- Sterile Neutrinos

- SuperWIMPs

Inherit the appropriate relic density from the decay of the NTL particle of the new theory

- WIMPlless

Appropriate relic density achieved by a suitable combination of masses and couplings

WHY “ANNIHILATIONS”?

X = DARK MATTER

SM = STANDARD MODEL PARTICLE

EARLY UNIVERSE

TODAY

$$\frac{dn_\chi}{dt} - 3Hn_\chi = -\langle\sigma v\rangle [n_\chi^2 - (n_\chi^{eq})^2]$$

$$\frac{dn_\chi}{dt} = -(\sigma v)_0 n_\chi^2$$

RELIC DENSITY (NR FREEZE-OUT)

ANNIHILATION FLUX

$$\Omega h^2 \approx \frac{3 \times 10^{-27} \text{ cm}^3 \text{ s}^{-1}}{\langle\sigma v\rangle}$$

$$\Phi_i(\Omega, E_i) = \frac{dN}{dE_i} \frac{\langle\sigma v\rangle}{8\pi m_\chi^2} \int_{\text{los}} \rho_\chi^2(l, \Omega) dl$$

Electroweak-scale cross sections can reproduce correct relic density.

Particle physics input from extensions of the Standard Model. Need to specify distribution of DM along the line of sight.

PIERI, GB, BRANCHINI 2009

The “GeV Excess”

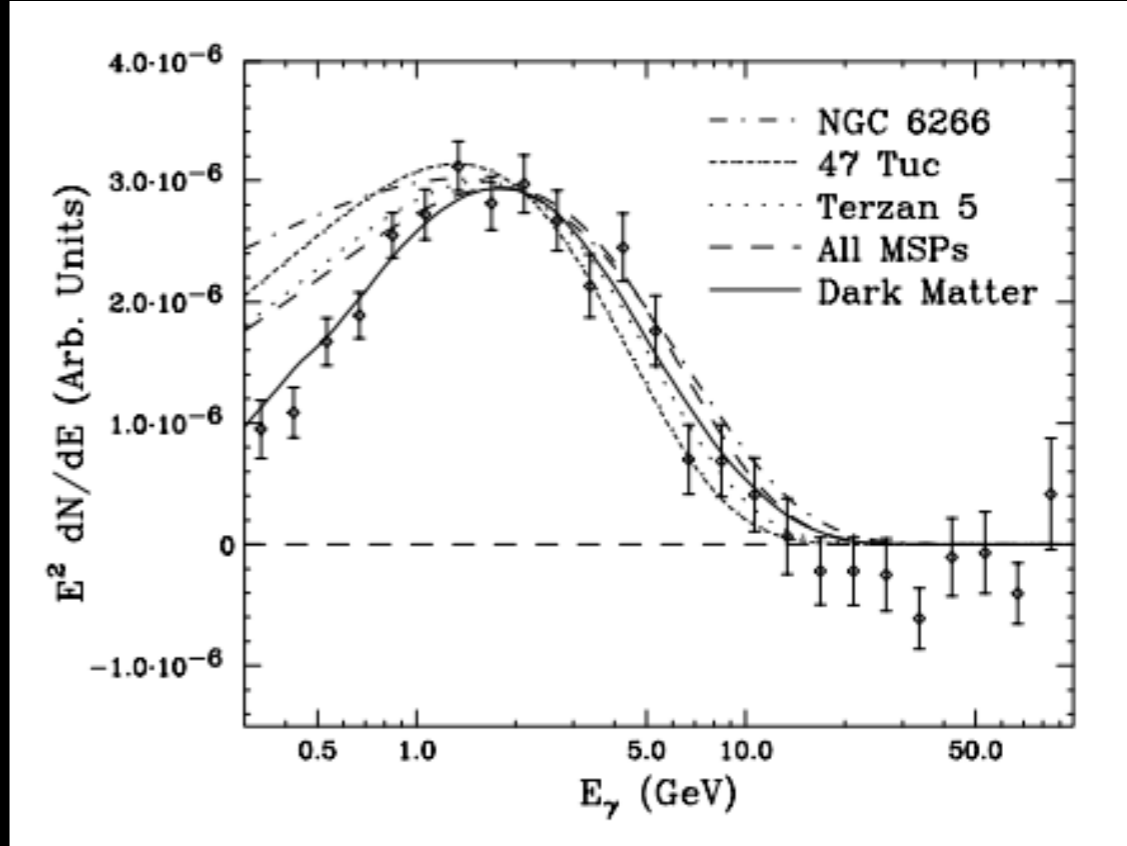

FIG. 9: The raw gamma-ray maps (left) and the residual maps after subtracting the best-fit Galactic diffuse model, 20 cm template, point sources, and isotropic template (right), in units of photons/cm²/s/sr. The right frames clearly contain a significant central and spatially extended excess, peaking at ~1-3 GeV. Results are shown in galactic coordinates, and all maps have been smoothed by a 0.25° Gaussian.

“Within these maps, we find the GeV excess to be robust and highly statistically significant, with a spectrum, angular distribution, and overall normalization that is in good agreement with that predicted by simple annihilating dark matter models”

Daylan et al. arXiv:1402.6703

The GeV excess

Calore, Bozorgnia, GB+ arXiv:1509.02164

High resolution simulated haloes (Eagle sim.) that satisfy observational constraints exhibit, in the inner few kiloparsecs, dark matter profiles shallower than those required to explain the GeV excess via dark matter annihilation.

Usual problem with ID:

Difficult to rule out 'Standard' Astro interpretation

Dark Matter Searches at the LHC

Suppose a new particle is found, we may measure its mass, couplings, LL on lifetime. But is this THE dark matter particle?

Example of Inverse DM problem at LHC

Inferring the relic density (thus the DM nature) of new particles from LHC data

The dream scenario:

FIG. 34. Particle spectrum for point LCC3. The stau-neutralino mass splitting is 10.8 GeV. The lightest neutralino is predominantly b -ino, the second neutralino and light chargino are predominantly W -ino, and the heavy neutralinos and chargino are predominantly Higgsino.

AD. FROM BALTZ ET AL (2005)

Example of Inverse DM problem at LHC

(example in the stau coannihilation region, 24 parms pMSSM)

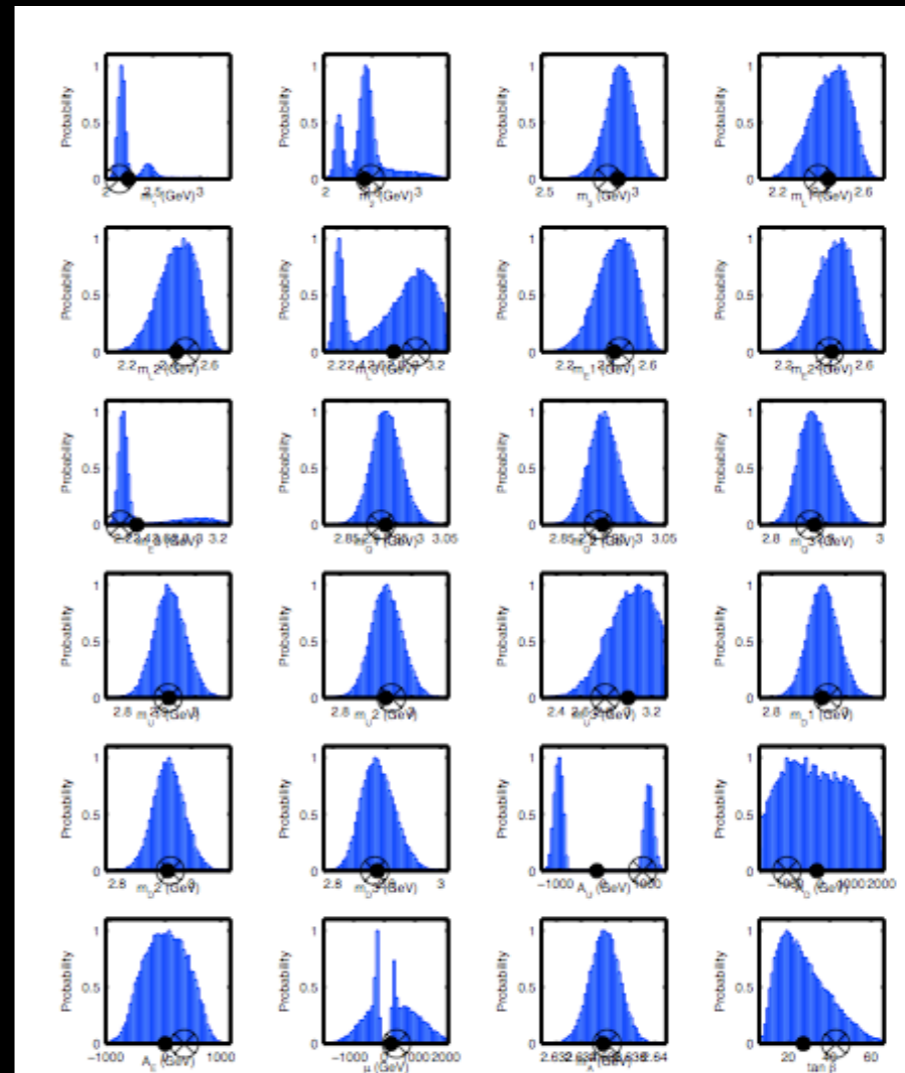

Mass	Benchmark value, μ	LHC error, σ
$m(\tilde{\chi}_1^0)$	139.3	14.0
$m(\tilde{\chi}_2^0)$	269.4	41.0
$m(\tilde{e}_R)$	257.3	50.0

DD+LHC: “Scaling” Ansatz

$$\frac{\rho_\chi}{\rho_{dm}} = \frac{\Omega_\chi}{\Omega_{dm}}$$

“If the neutralino contributes $x\%$ of the local dark matter density ρ_{dm} , then it also contributes $x\%$ of the total dark matter abundance Ω_{dm} ”

DD+LHC

If this discovery program works, we would validate our particle physics and cosmological model. If it doesn't, it could point towards additional forms of dark matter, or modified cosmology.

Conclusions

- *Huge* Theoretical and experimental effort towards the identification of DM. It is OK to be skeptical about current claims of detection..
- Indirect Detection more and more constrained, though there are some tantalizing hints
- DM Direct Detection looks promising. Info from other experiments is needed to determine DM particle properties
- Run II of the LHC will soon provide crucial information! Even in case of detection, complementary information from (in)direct searches (or new accelerators!) likely necessary to *identify* DM
- WIMP paradigm well motivated, but not a dogma. Important to diversify DM searches (light DM, axions, sterile neutrinos etc.), as WIMPs will soon be discovered or slowly abandoned..
