
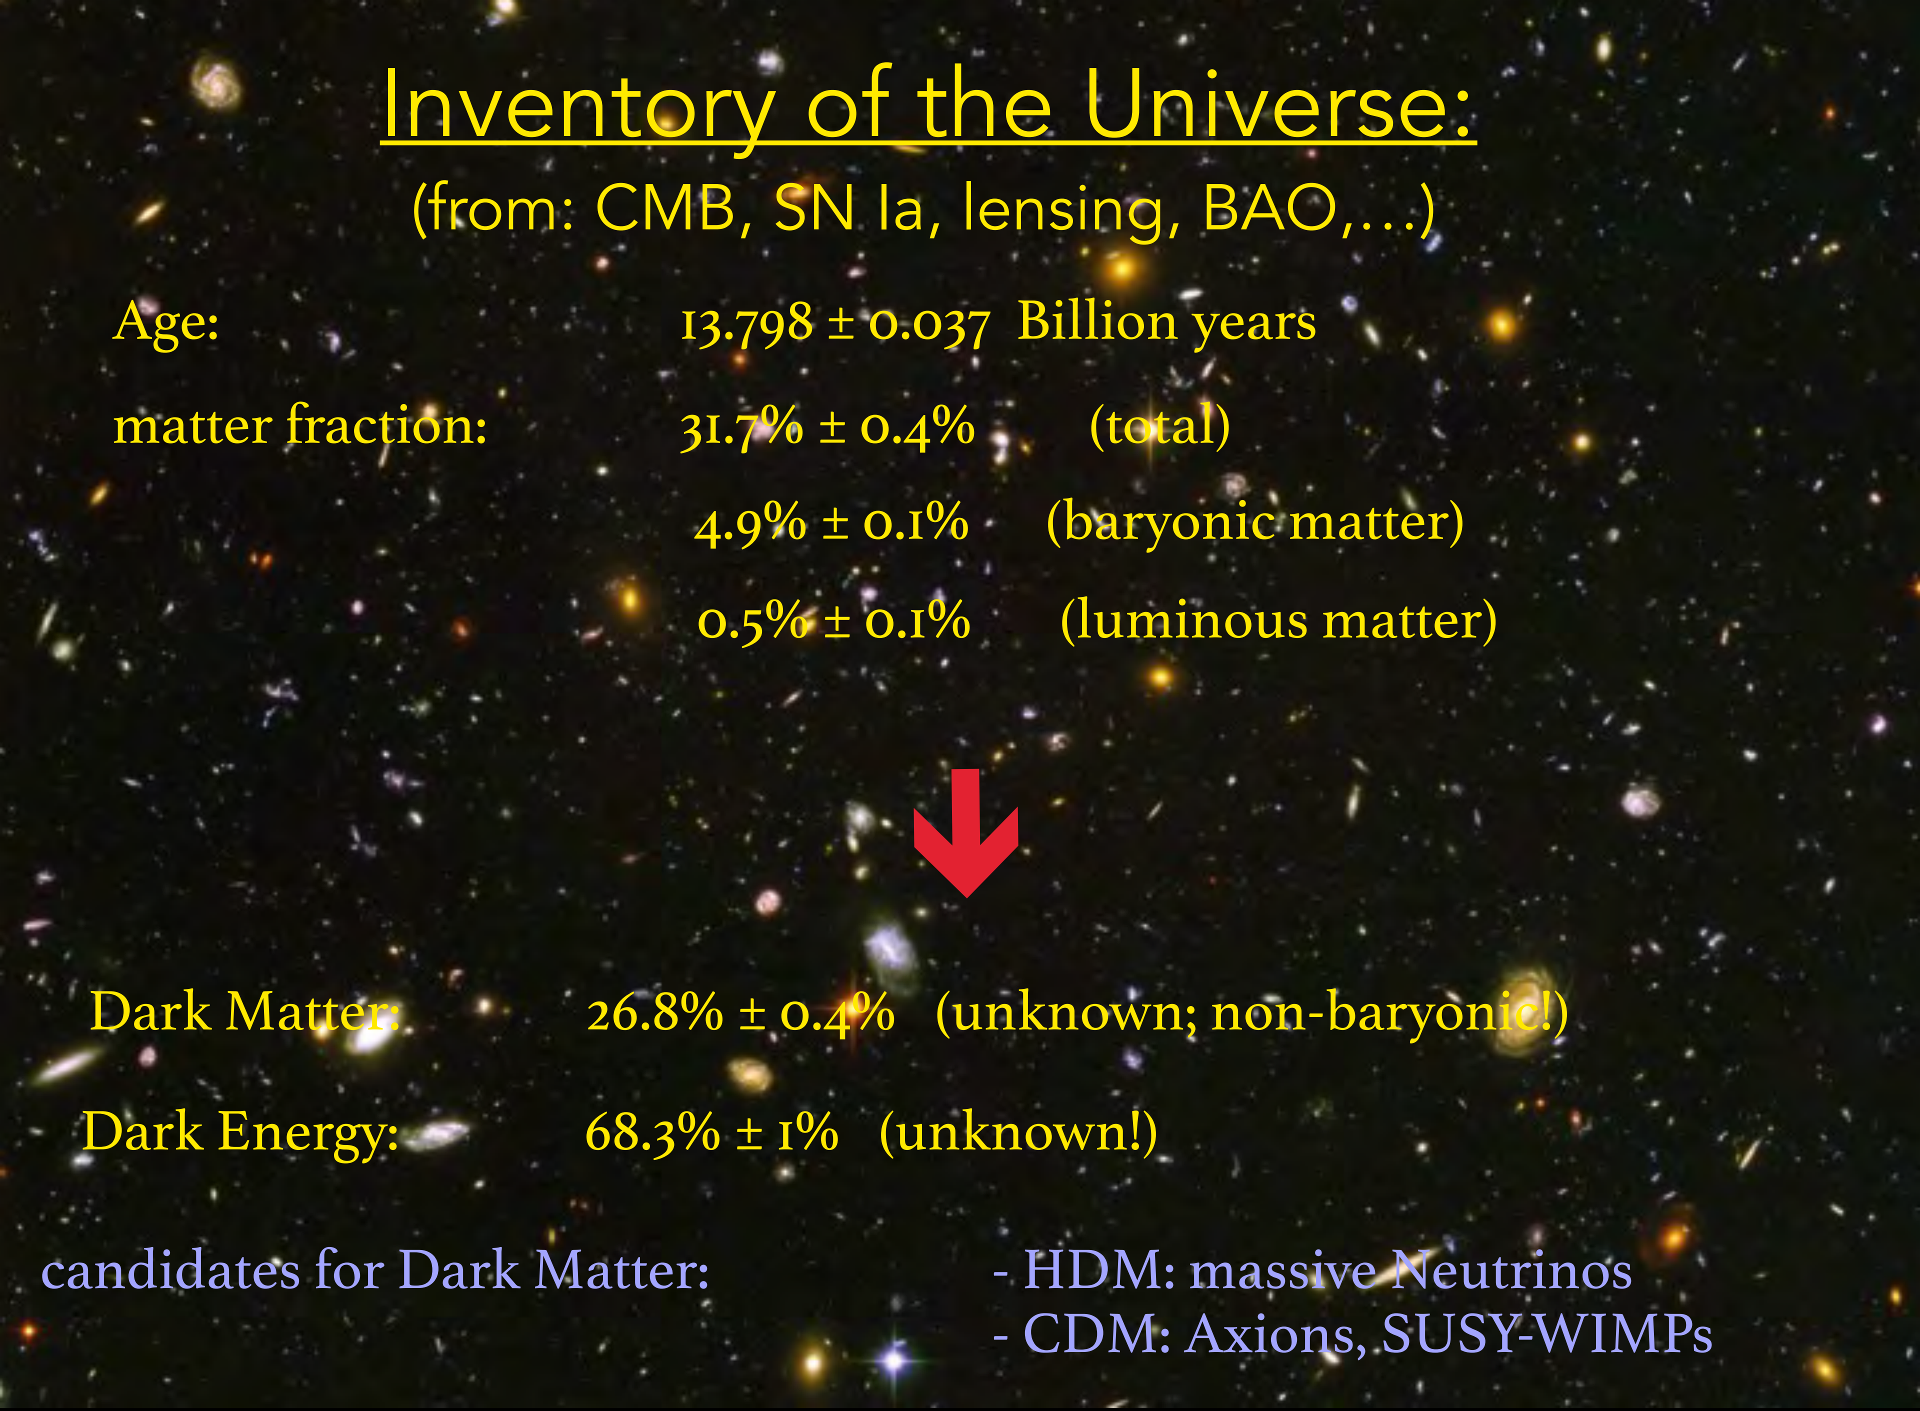
Dark Matter

(and Dark Energy)

- Inventory of the Universe
- the expanding Universe
- Evidence for the Existence of Dark Matter:
  - rotational curves of spiral Galaxies
  - microwave background and cosmic energy density
  - galaxy clusters
- cosmological constraints
- DM: particle candidates and searches
- example: the CRESST experiment



Inventory of the Universe:

(from: CMB, SN Ia, lensing, BAO,…)

Age:	13.798 ± 0.037	Billion years
matter fraction:	31.7% ± 0.4%	(total)
	4.9% ± 0.1%	(baryonic matter)
	0.5% ± 0.1%	(luminous matter)

↓

Dark Matter:	26.8% ± 0.4%	(unknown; non-baryonic!)
Dark Energy:	68.3% ± 1%	(unknown!)

candidates for Dark Matter:
- HDM: massive Neutrinos
- CDM: Axions, SUSY-WIMPs

Inventory of the Universe (PLANCK):

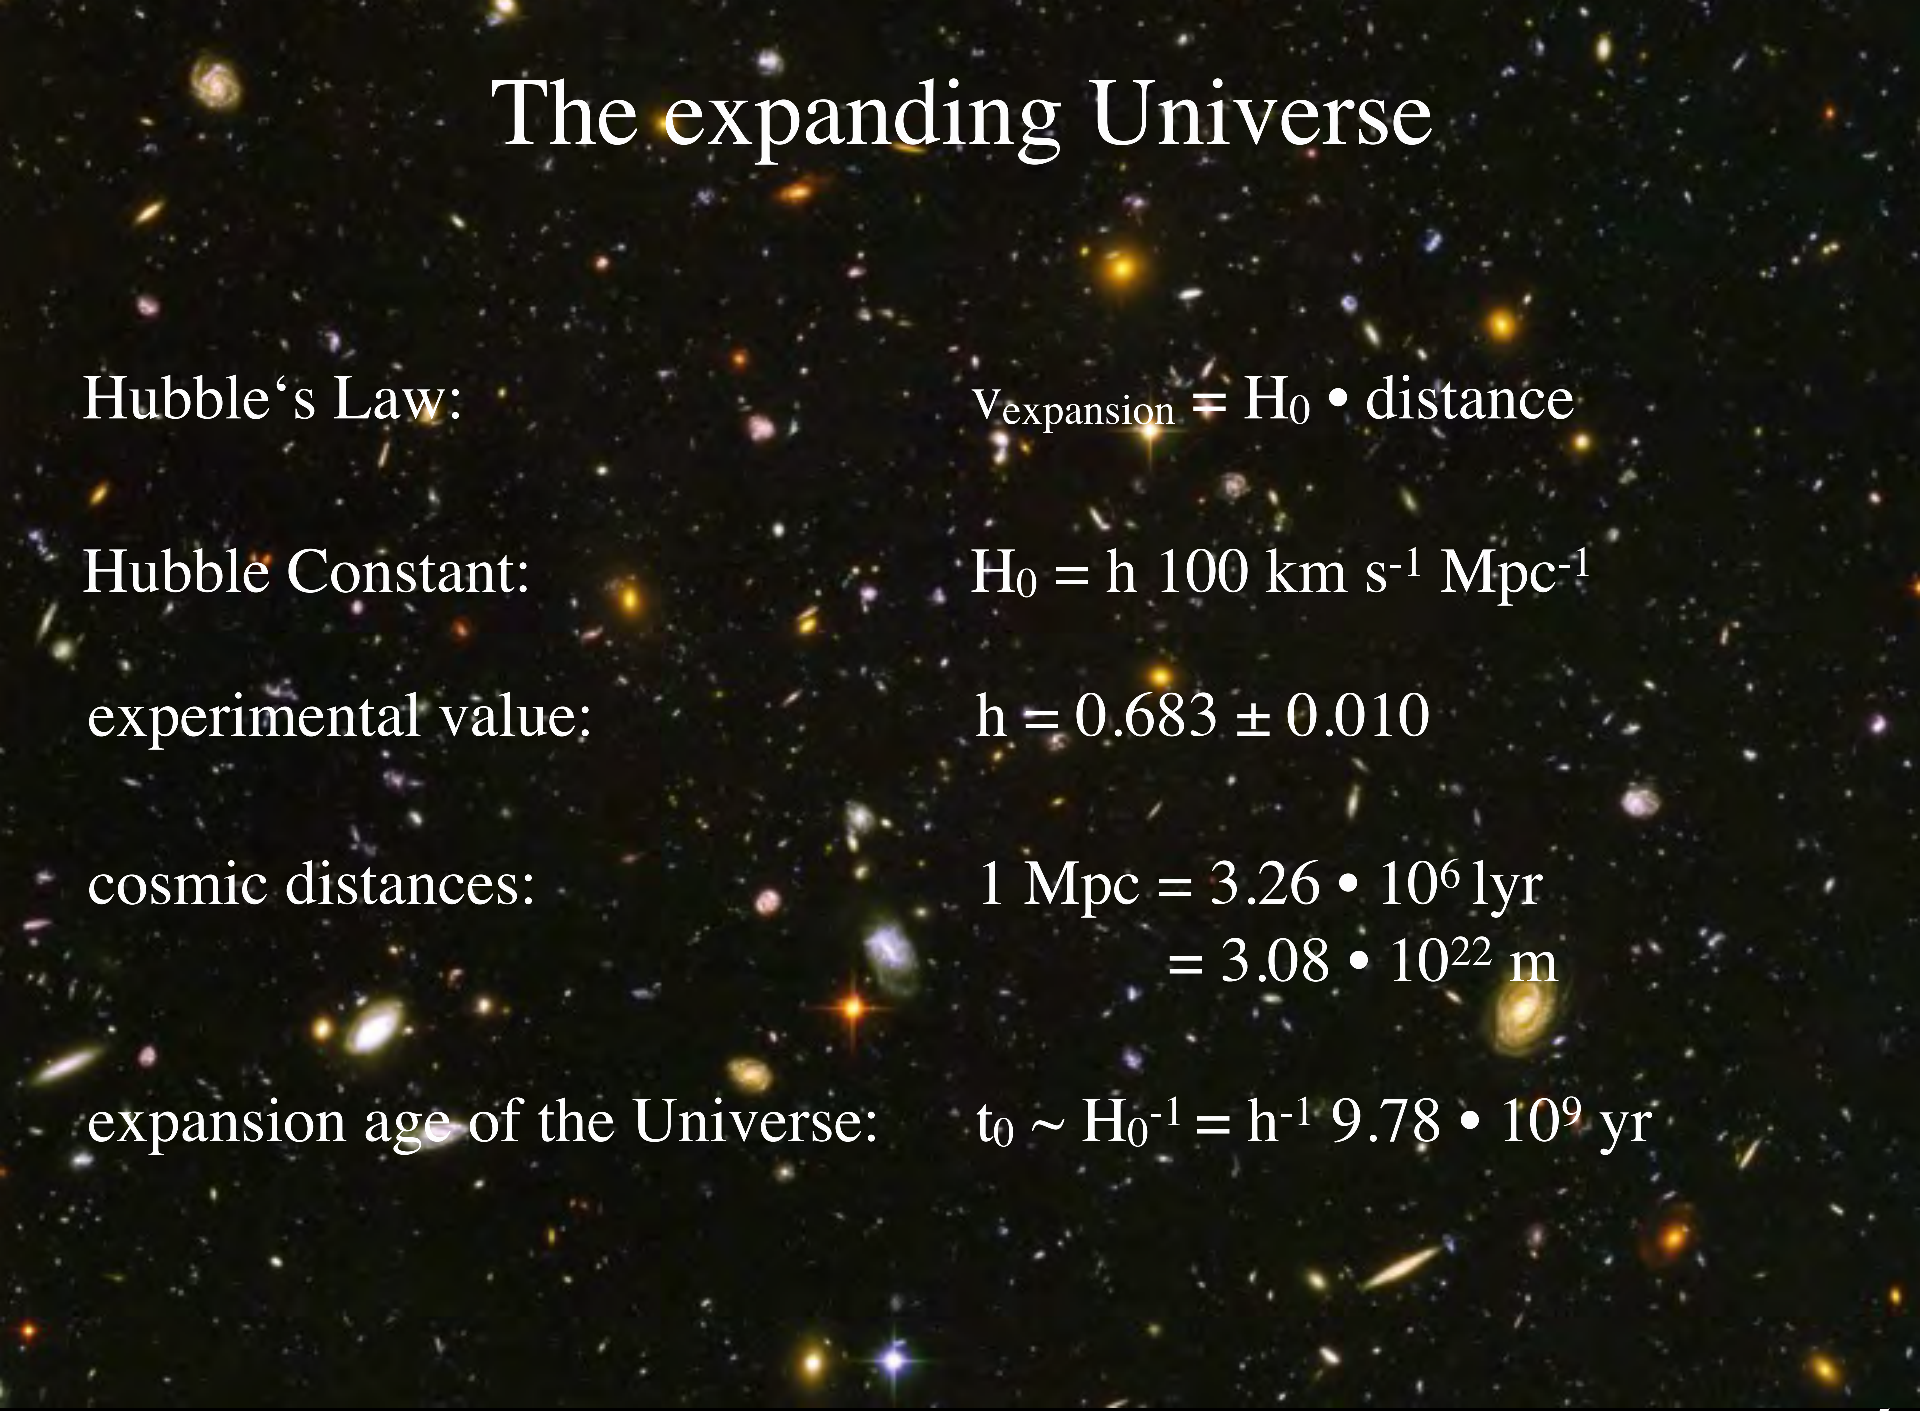
it doesn’t

matter



The expanding Universe

Hubble‘s Law: $v_{expansion} = H_0 \bullet \text{distance}$

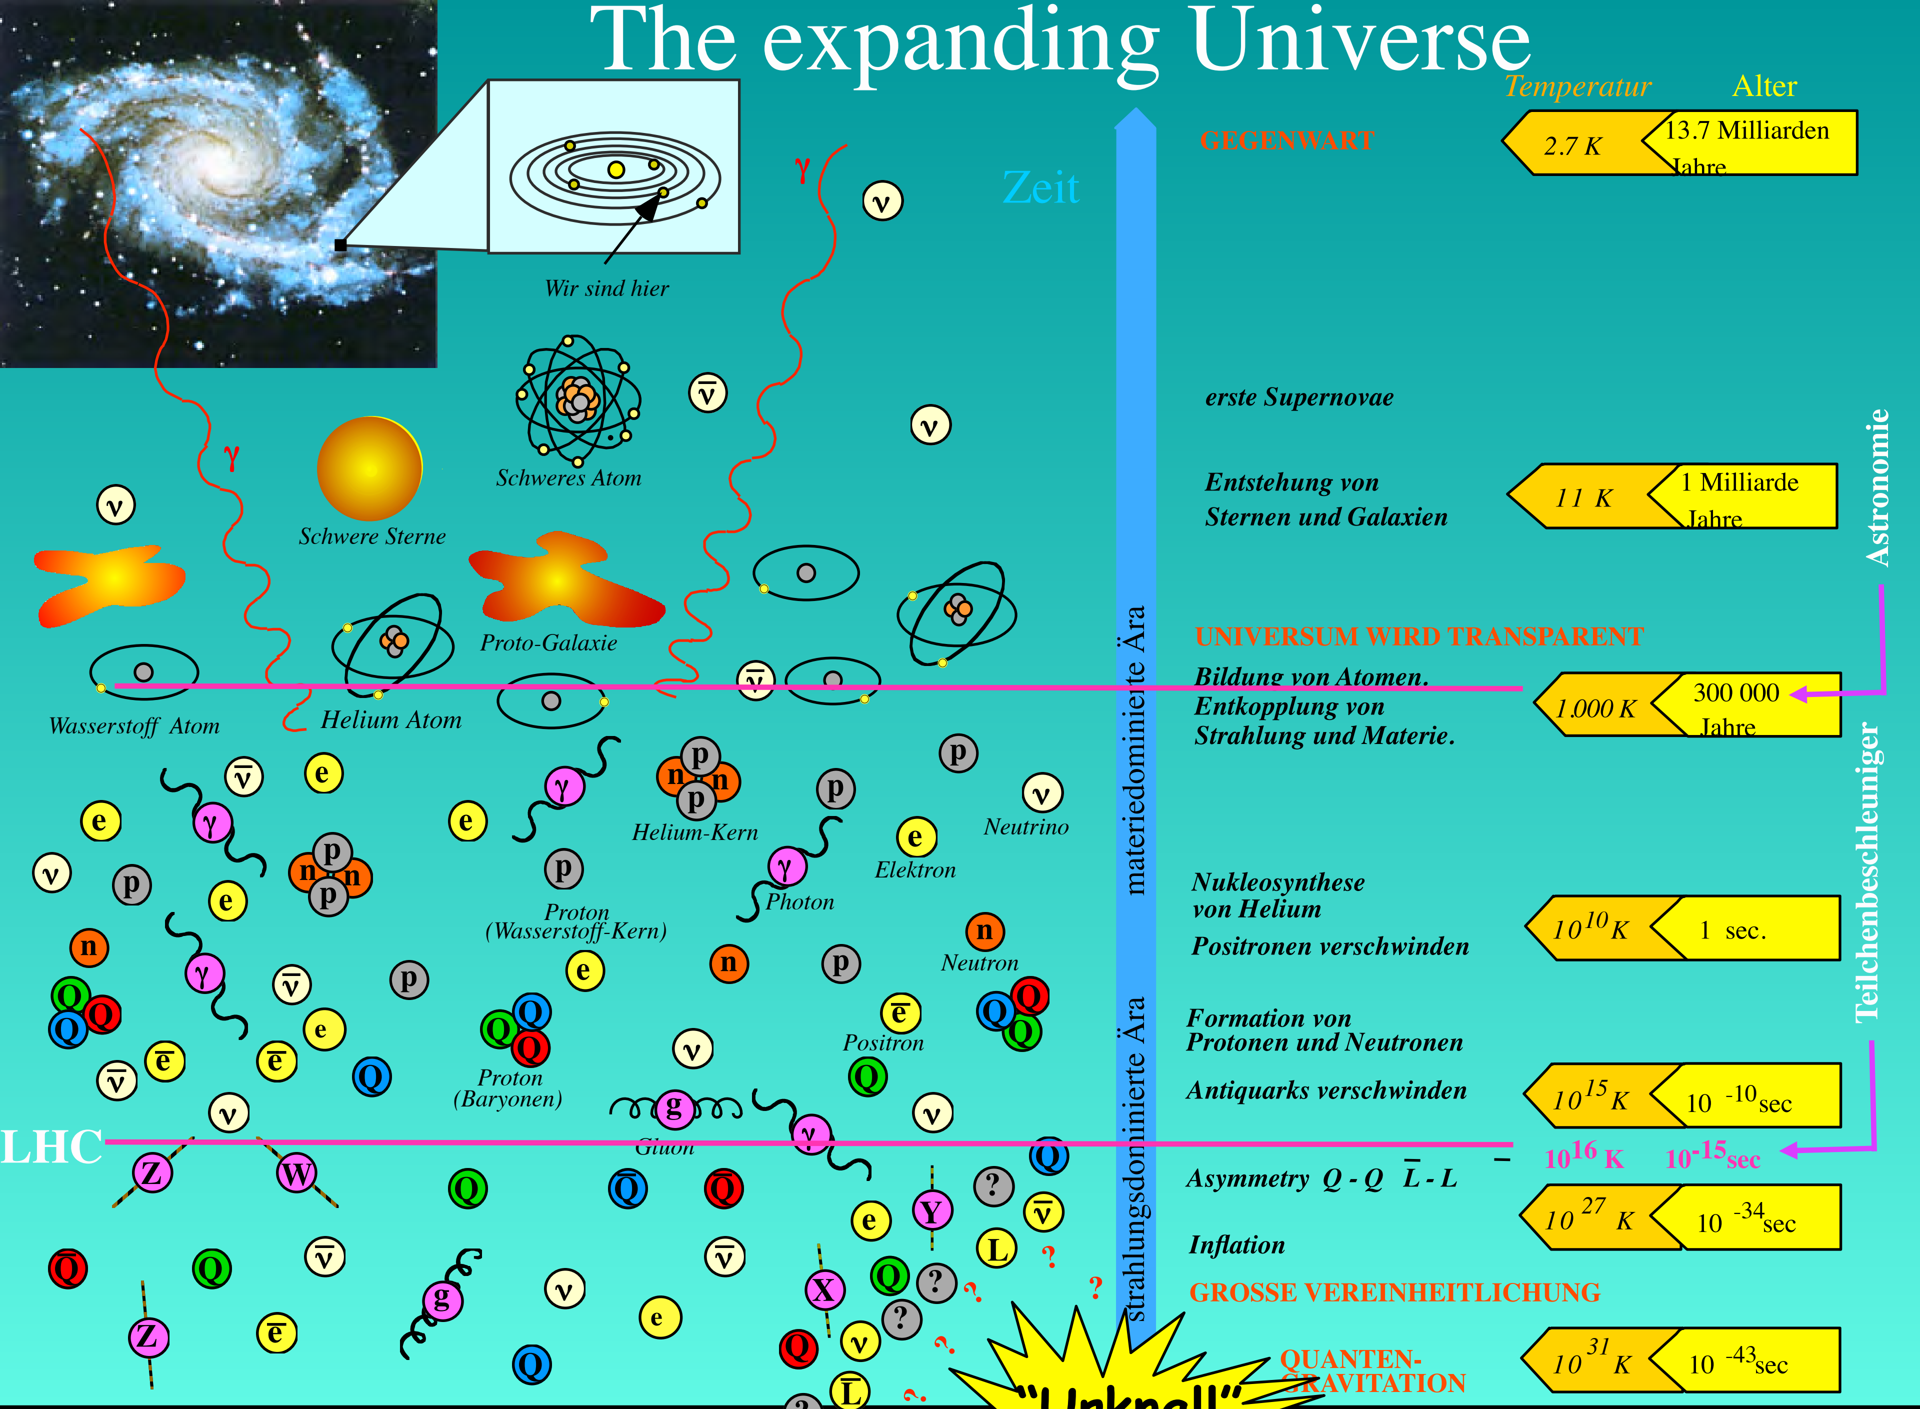
Hubble Constant: $H_0 = h\ 100\ \text{km s}^{-1}\ \text{Mpc}^{-1}$

experimental value: $h = 0.683 \pm 0.010$

cosmic distances: $1\ \text{Mpc} = 3.26 \bullet 10^6\ \text{lyr}$
$= 3.08 \bullet 10^{22}\ \text{m}$

expansion age of the Universe: $t_0 \sim H_0^{-1} = h^{-1}\ 9.78 \bullet 10^9\ \text{yr}$

The expanding Universe



Temperatur — Alter

GEGENWART — *2.7 K* — 13.7 Milliarden Jahre

Inflation

GROSSE VEREINHEITLICHUNG

QUANTEN-GRAVITATION — 10^{31} K — 10^{-43} sec

The expanding Universe

components of cosmic matter- and energy-density

contribution ρ of matter components to total density of the universe: $\Omega = \rho / \rho_{\text{crit}}$

critical density: $\rho_{crit} = 3H_0^2 / (8\pi G_N)$

$$= \mathrm{h}^2\ 1.88 \times 10^{-29}\ \mathrm{g\ cm^{-3}}$$

$\Omega = 1$: euclidian geometry („flat universe“)

$\Omega < 1$: negative curvature of space („open universe“)

$\Omega > 1$: positive curvature of space („closed universe“)

Global Cosmic Geometry

positive curvature
$k = +1$
$\Omega_{tot} > 1$

negative curvature
$k = -1$, $\Omega_{tot} < 1$

Euclidean (flat)
$k = 0$
$\Omega_{tot} = 1$

Favored by
- ➡ Inflationary cosmological models
- ➡ Recent cosmic microwave background measurements

evidence for existence of Dark Matter

1. cosmological arguments

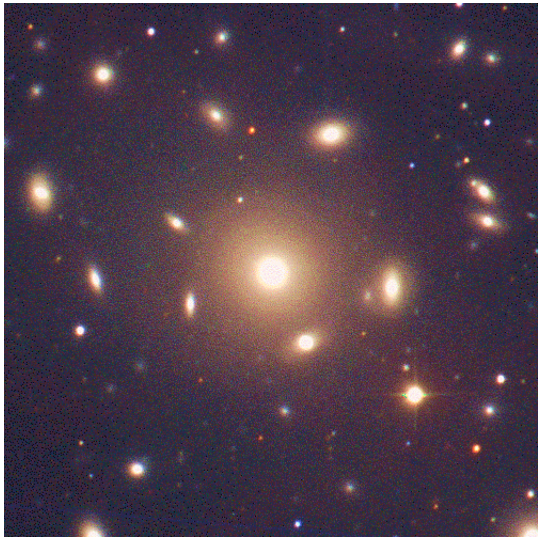
Ω_{tot} = 1 because,
in an expanding universe,
Ω_{tot} quickly develops away from 1,
towards 0 or ∞.

if today $\Omega_{tot} \sim 1$,
then $\Omega_{tot} = 1$ is most probable
exact solution.

evidence for existence of Dark Matter

2. Dark Matter in galaxy clusters (Zwicky 1933):

a gravitationally bound many-particle system in equilibrium obeys the Virial Theorem.



Coma Galaxy Cluster

Virial Theorem: $2\left\langle E_{kin}\right\rangle = -\left\langle E_{grav}\right\rangle$

$$E_{kin} = mv^2/2, \qquad E_{grav} = G_N M_r m/r$$

$$\Rightarrow \quad \left\langle \mathrm{v}^2 \right\rangle \approx G_N M \left\langle r^{-1} \right\rangle$$

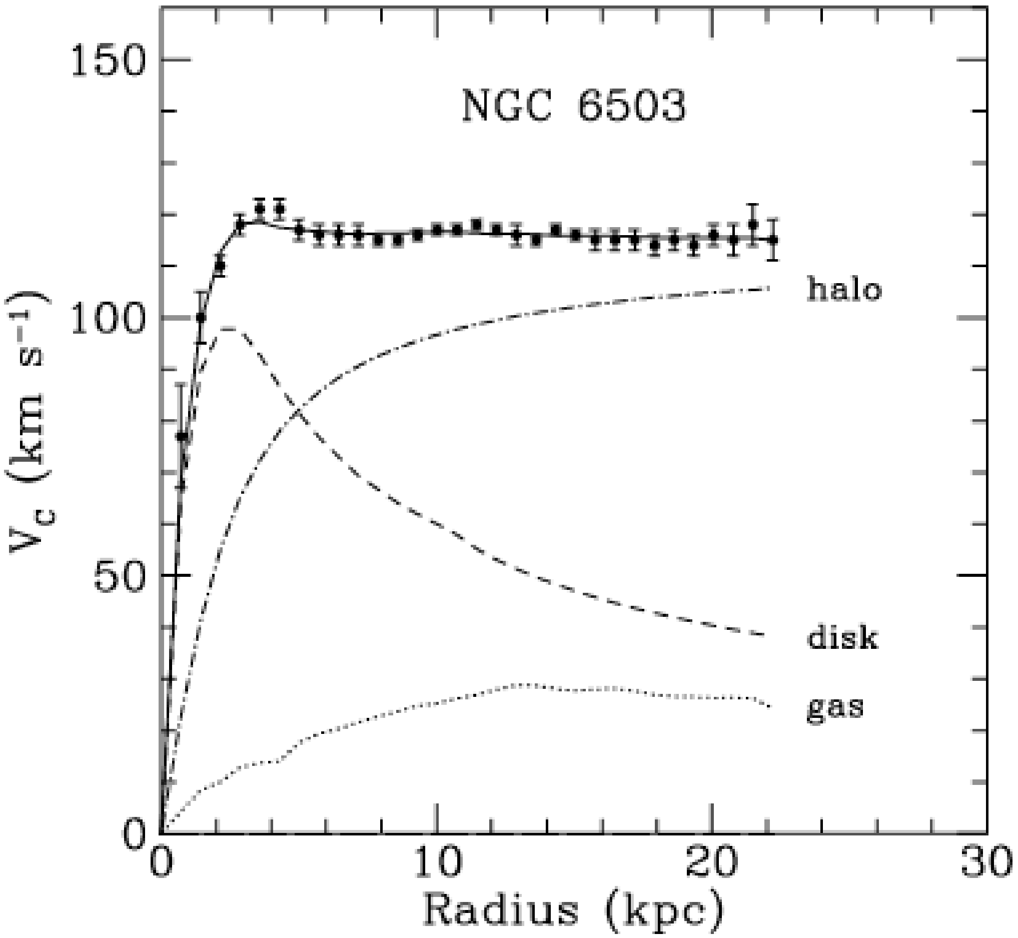
measurement of dispersion of velocity and geometrical size provides estimate of M (total mass)

result: M ~ 400 • visible mass!

(not commonly believed in for long!)

evidence for existence of Dark Matter

3. rotational curves of spiral galaxies



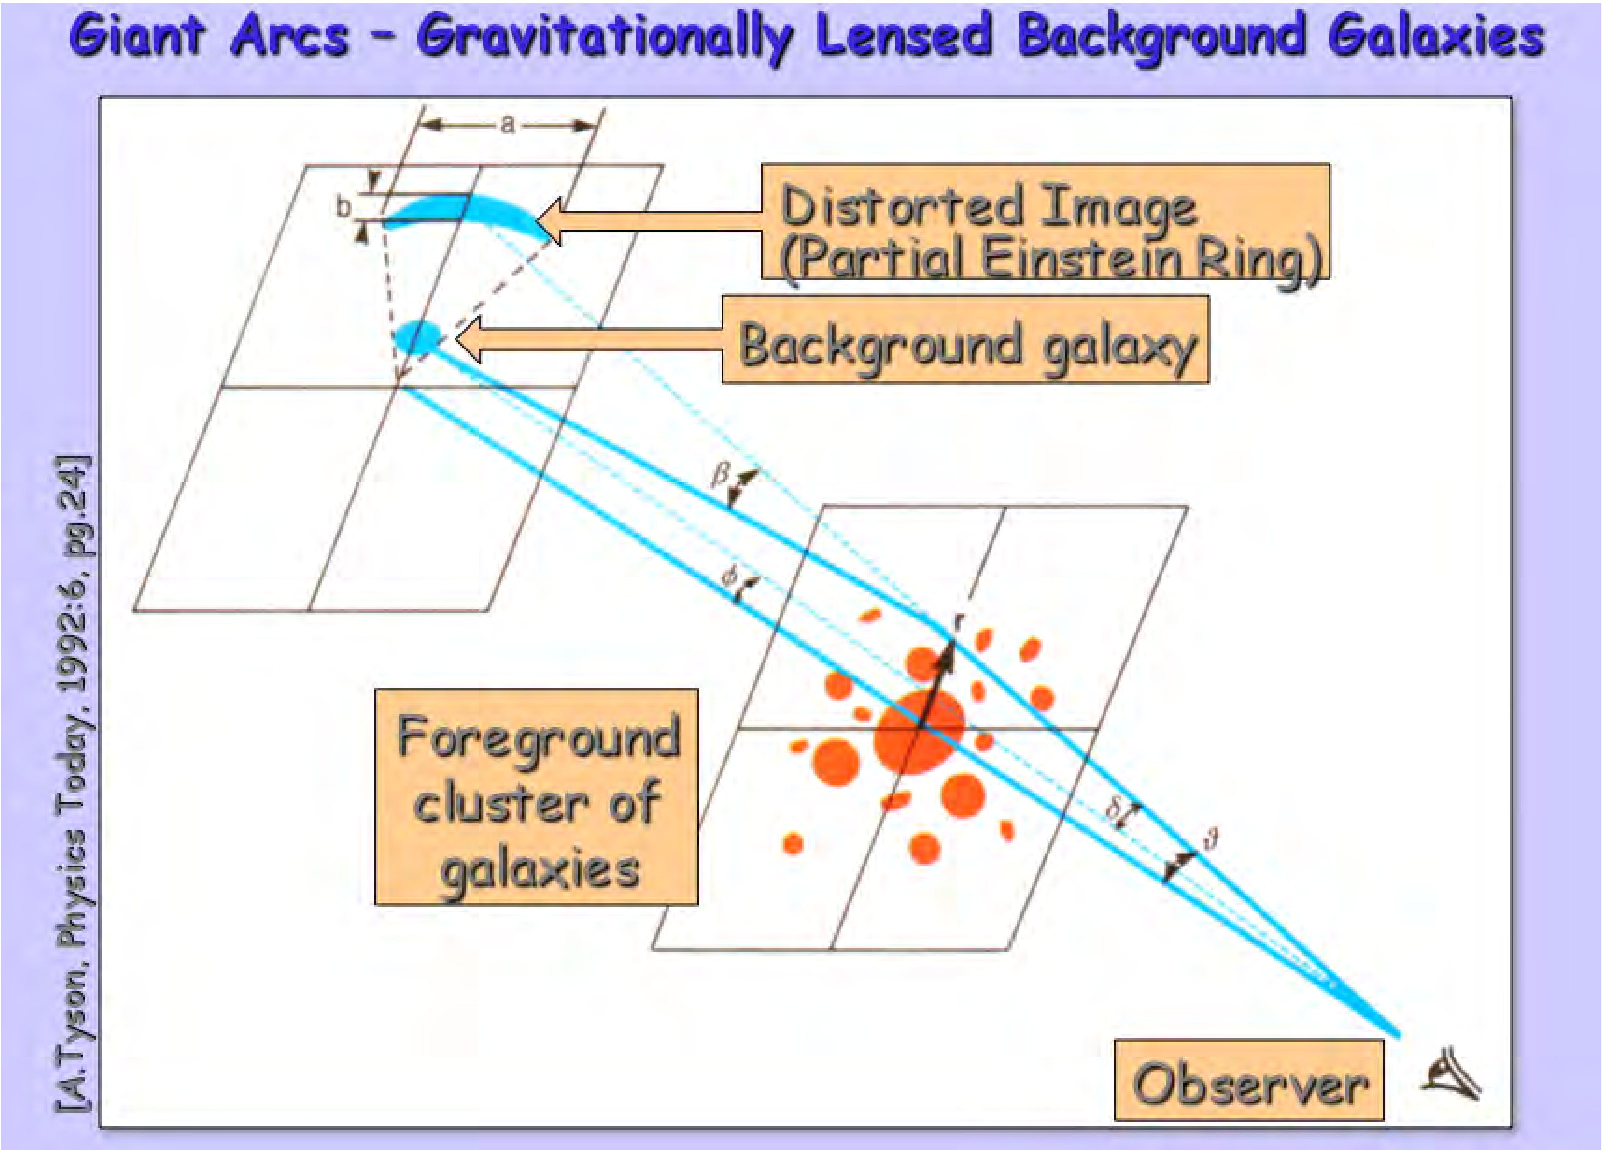
- expectation outside of galactic centre (Kepler): $\mathrm{v}_{\mathrm{rot}} = \sqrt{G_N M / r}$
- measurement: 21 cm emission line of neutral Hydrogen
  (possible to much larger distances than optical observations)
- result: ~constant distribution up to largest distances

—> „spherical halo" of Dark Matter (not only in disk !)

- in our own galaxy:
  $\mathrm{v}_{\mathrm{rot}}$ (plateau) ~ 220 km s^{-1} ;
  halo with ~300 MeV cm^{-3}
  (ca. 1 H-Atom per 3 cm^{3} !)

evidence for existence of Dark Matter

4. galaxy clusters, gravitational lensing

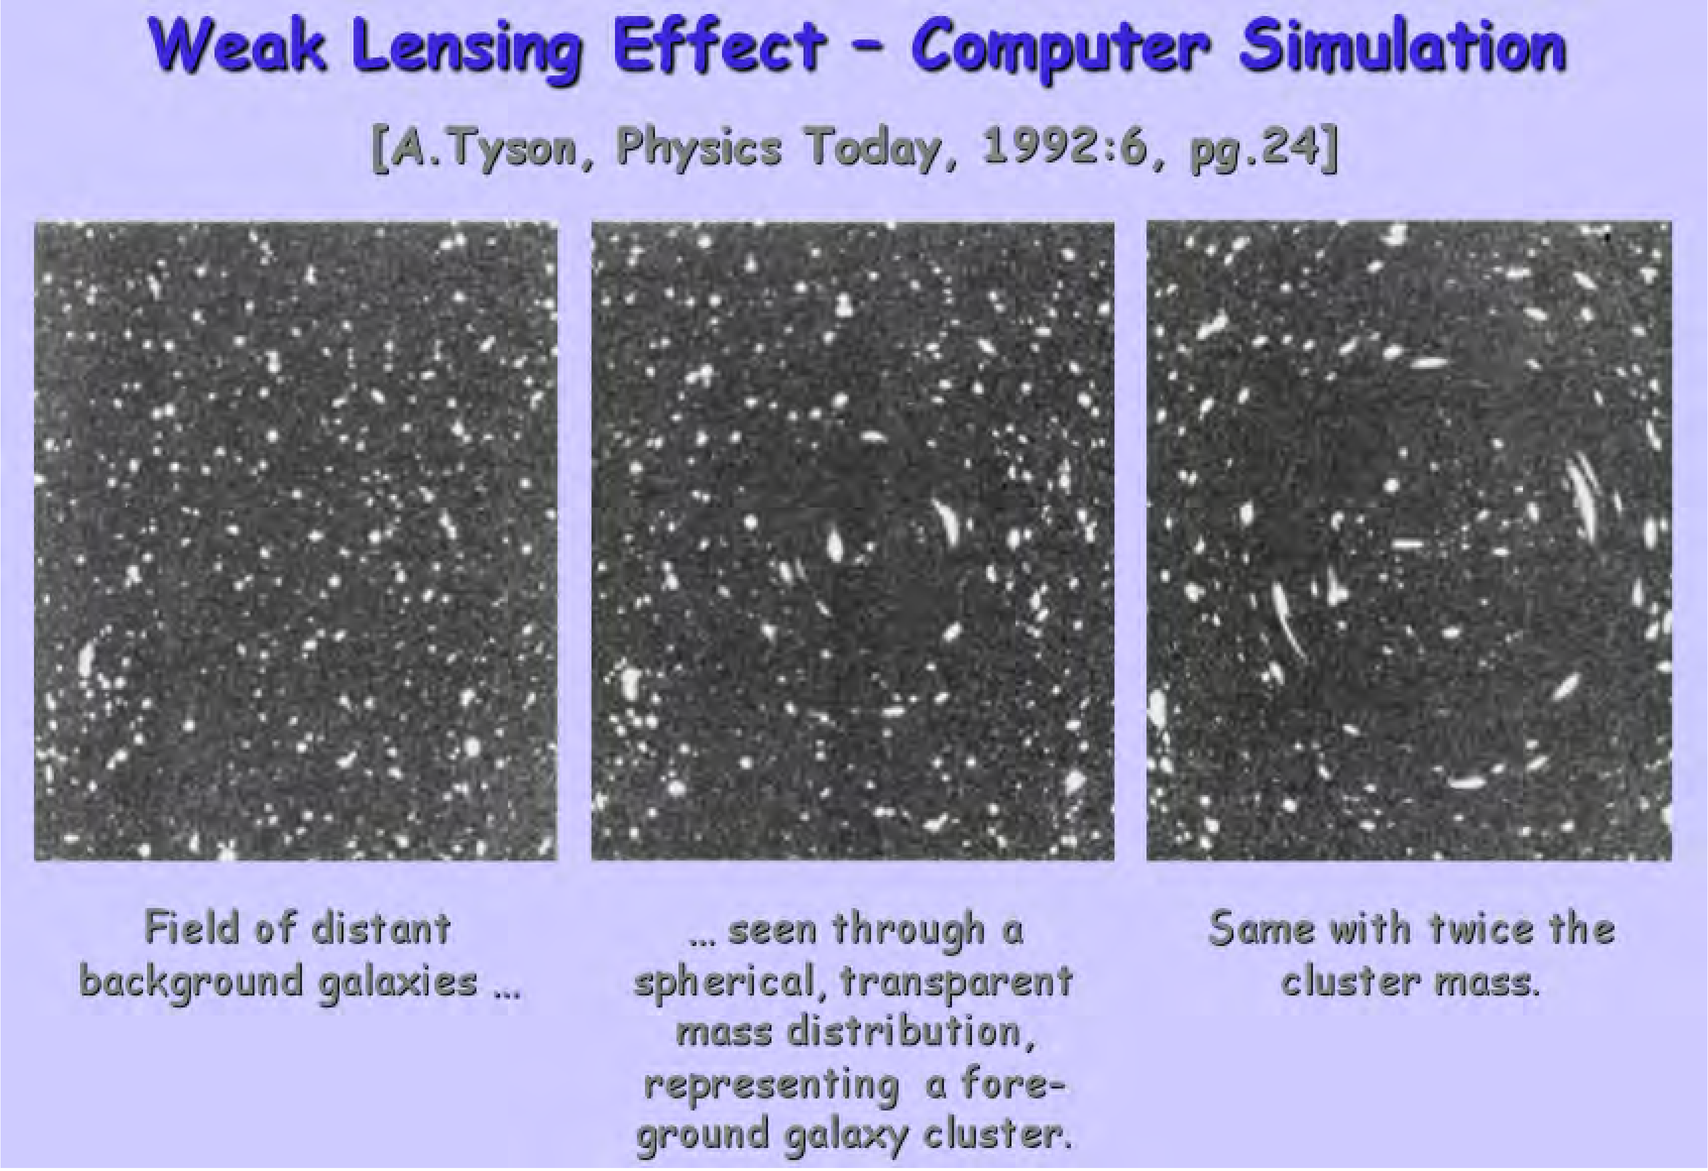


Giant Arcs - Gravitationally Lensed Background Galaxies

[A.Tyson, Physics Today, 1992:6, pg.24]

evidence for existence of Dark Matter

4. galaxy clusters, gravitational lensing



Weak Lensing Effect - Computer Simulation

[A.Tyson, Physics Today, 1992:6, pg.24]

Field of distant background galaxies ...

... seen through a spherical, transparent mass distribution, representing a foreground galaxy cluster.

Same with twice the cluster mass.

evidence for existence of Dark Matter

4. galaxy clusters, gravitational lensing

... agrees with large mass/light ratio resulting from Zwicky's method!

cosmological boundary conditions

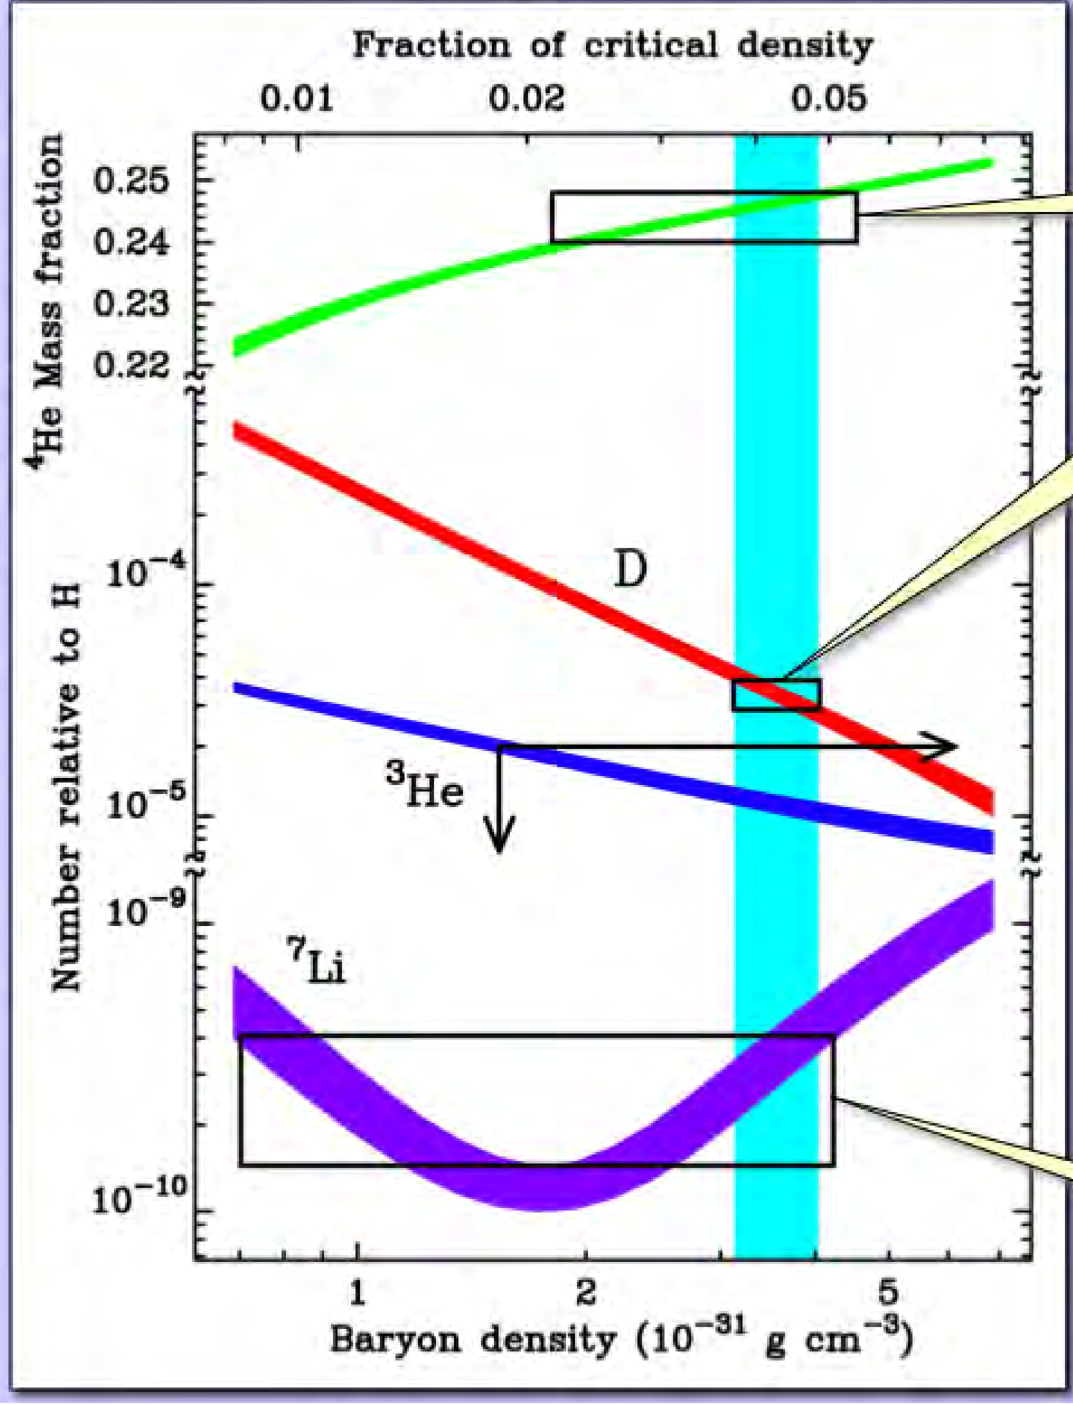
could Dark Matter be composed of hadronic,
non-luminous matter, as e.g. neutron stars,
cold molecular hydrogen clouds, or Black Holes?

No!
reason: baryon density of universe
is limited by so-called „Big Bang Nucleosynthesis:“

about 3 minutes after the Big Bang,
Helium (22%-25% of total mass)
as well as traces of D, He^3und Li^7 are created
from protons and neutrons.

their relative amounts only depend on
cosmic density of baryons!

BBN Concordance



Helium 4

Deuterium

Lithium

Cosmic baryon density implied by deuterium abundance:

$\Omega_B h^2 = 0.019 \pm 0.0024$

[astro-ph/9903300]

cosmological boundary conditions

structure formation

Standard Theory of cosmic structure formation:

- at an early stage, the universum was almost entirely homogenous...
- except of tiny density modulations, leading to conglomeration (by gravitation) of mass and built-up of galaxies.
- modulations originate from quantum fluctuations, which blew up, in a period of exponential expansion („inflationary universe“), to macroskopic scales

cosmological boundary conditions

structure formation

- amplitude of density fluctuations at an early stage (e.g. at decoupling of photons, about 300.000 years after Big Bang) reveals composition of matter and energy of early universe

- measurements of granularity of cosmic (2.7 K) microwave background (COBE; WMAP; Planck) shows: these amplitudes are too small to explain today's structure, if only baryonic matter and photons present.

- weakly interacting matter would work best, not being influenced by (electromagnetic) radiation.

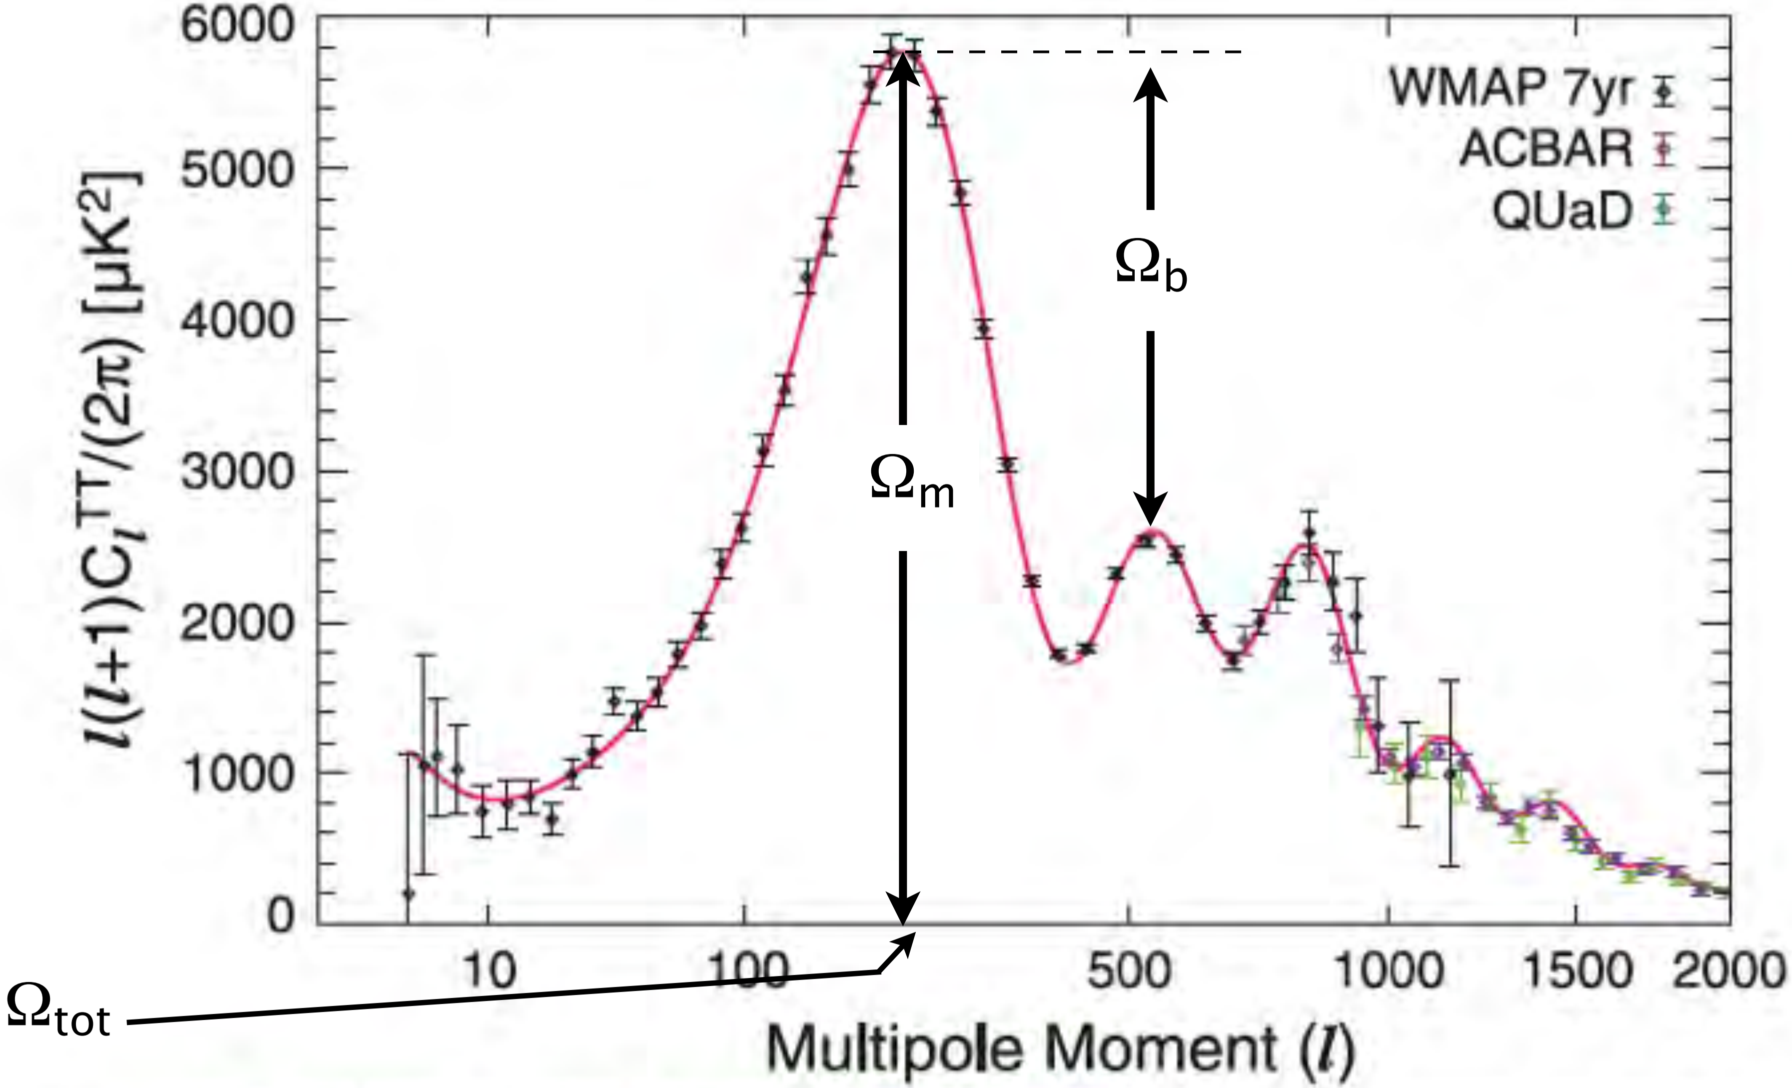
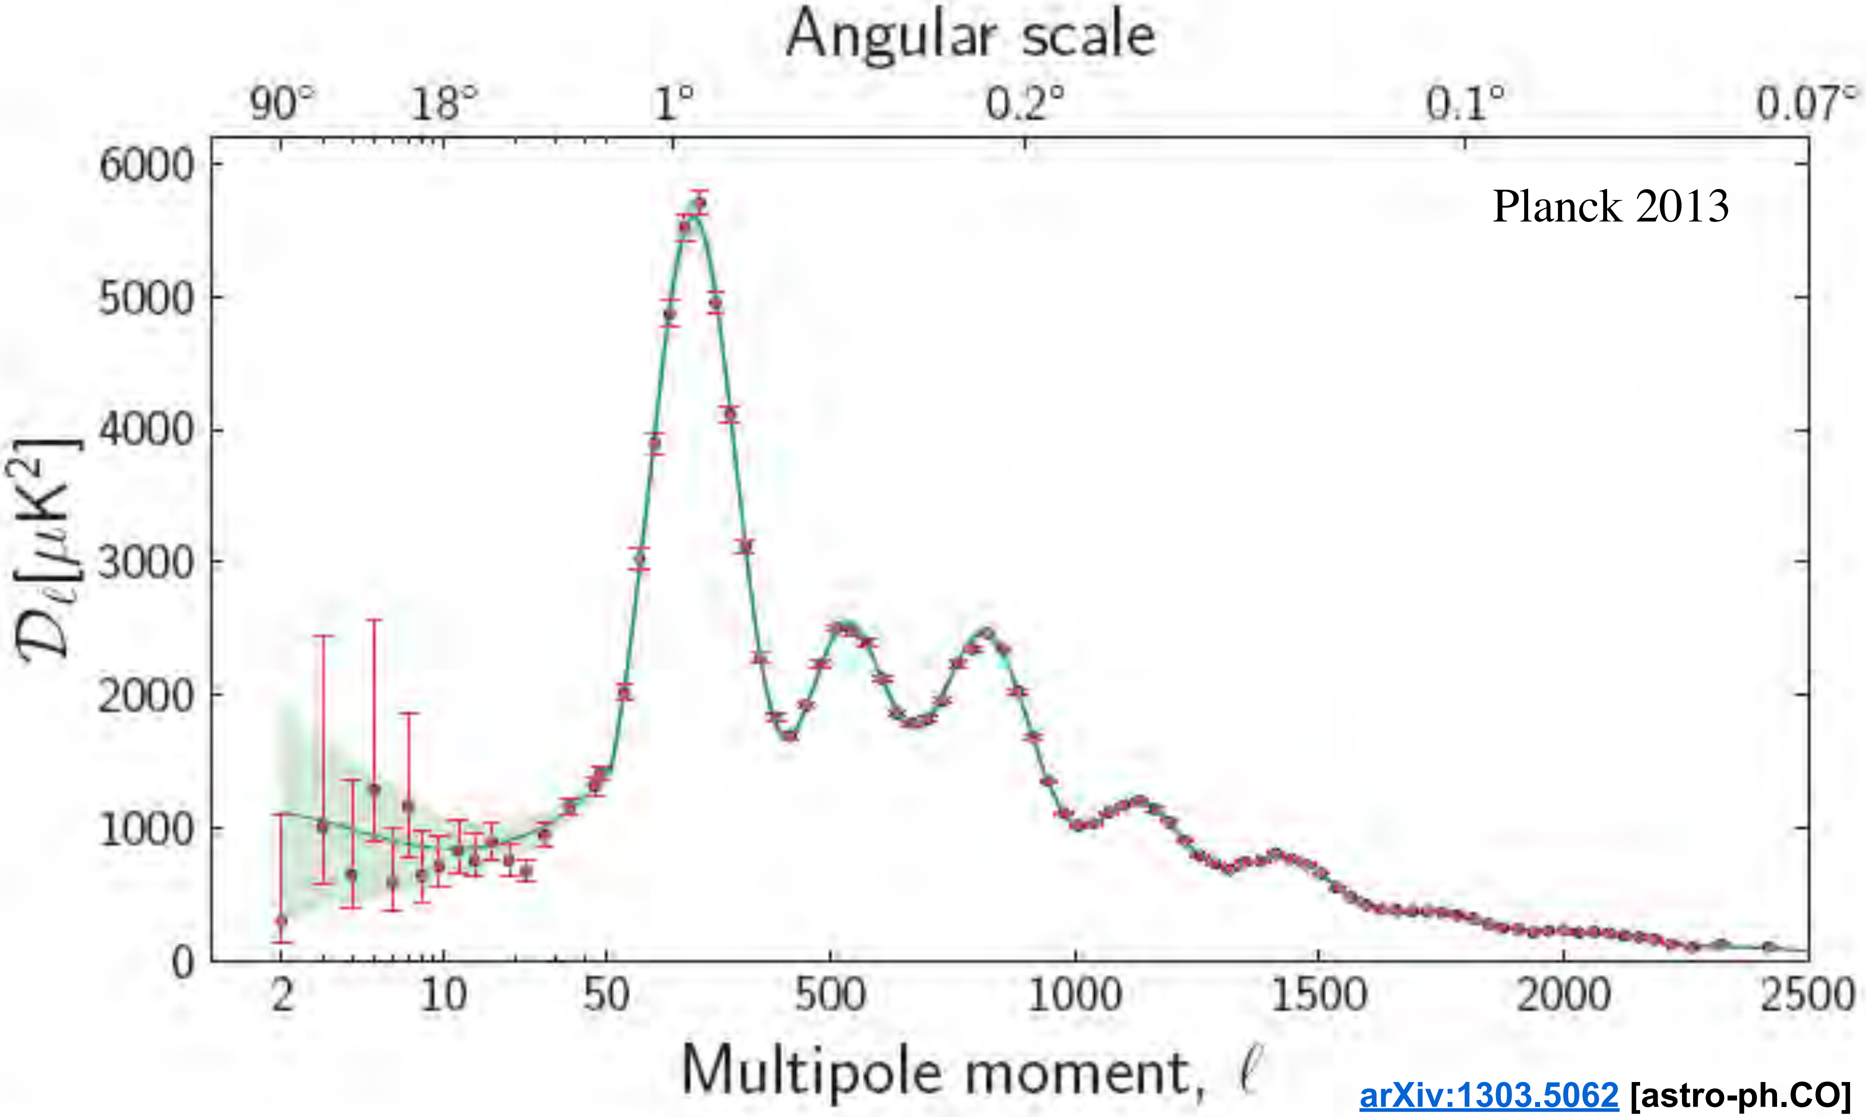
arXiv:1001.4538 [astro-ph]

Komatsu et al.



The *WMAP* 7-year temperature power spectrum (Larson et al. 2010), along with the temperature power spectra from the ACBAR (Reichardt et al. 2009) and QUaD (Brown et al. 2009) experiments. We show the ACBAR and QUaD data only at $l \geq 690$, where the errors in the *WMAP* power spectrum are dominated by noise. We do not use the power spectrum at $l > 2000$ because of a potential contribution from the SZ effect and point sources. The solid line shows the best-fitting 6-parameter flat ΛCDM model to the *WMAP* data alone (see the 3rd column of Table 1 for the maximum likelihood parameters).



arXiv:1303.5062 [astro-ph.CO]

Fig. 19. The temperature angular power spectrum of the primary CMB from *Planck*, showing a precise measurement of seven acoustic peaks, that are well fit by a simple six-parameter ΛCDM theoretical model (the model plotted is the one labelled [Planck+WP+highL] in Planck Collaboration XVI (2013)). The shaded area around the best-fit curve represents cosmic variance, including the sky cut used. The error bars on individual points also include cosmic variance. The horizontal axis is logarithmic up to $\ell = 50$, and linear beyond. The vertical scale is $\ell(\ell+1)C_l/2\pi$. The measured spectrum shown here is exactly the same as the one shown in Fig. 1 of Planck Collaboration XVI (2013), but it has been rebinned to show better the low-ℓ region.

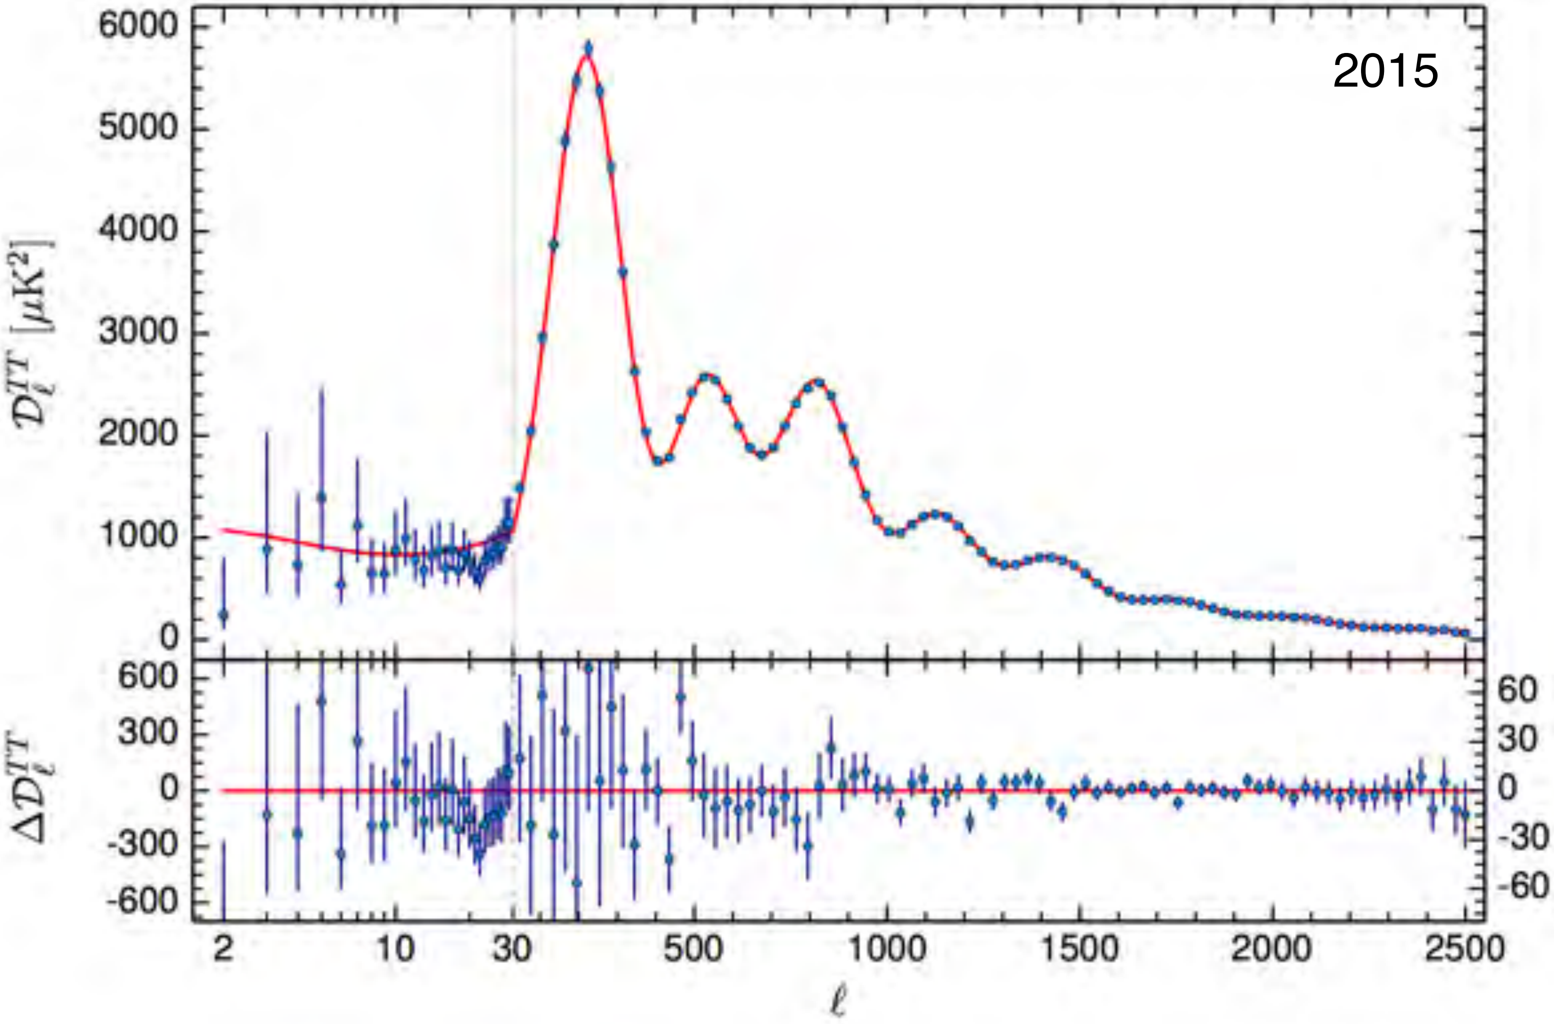


Fig. 1. The *Planck* 2015 temperature power spectrum. At multipoles $\ell \geq 30$ we show the maximum likelihood frequency averaged temperature spectrum computed from the `Plik` cross-half-mission likelihood with foreground and other nuisance parameters determined from the MCMC analysis of the base ΛCDM cosmology. In the multipole range $2 \leq \ell \leq 29$, we plot the power spectrum estimates from the `Commander` component-separation algorithm computed over 94% of the sky. The best-fit base ΛCDM theoretical spectrum fitted to the *Planck* TT+lowP likelihood is plotted in the upper panel. Residuals with respect to this model are shown in the lower panel. The error bars show $\pm 1\,\sigma$ uncertainties.

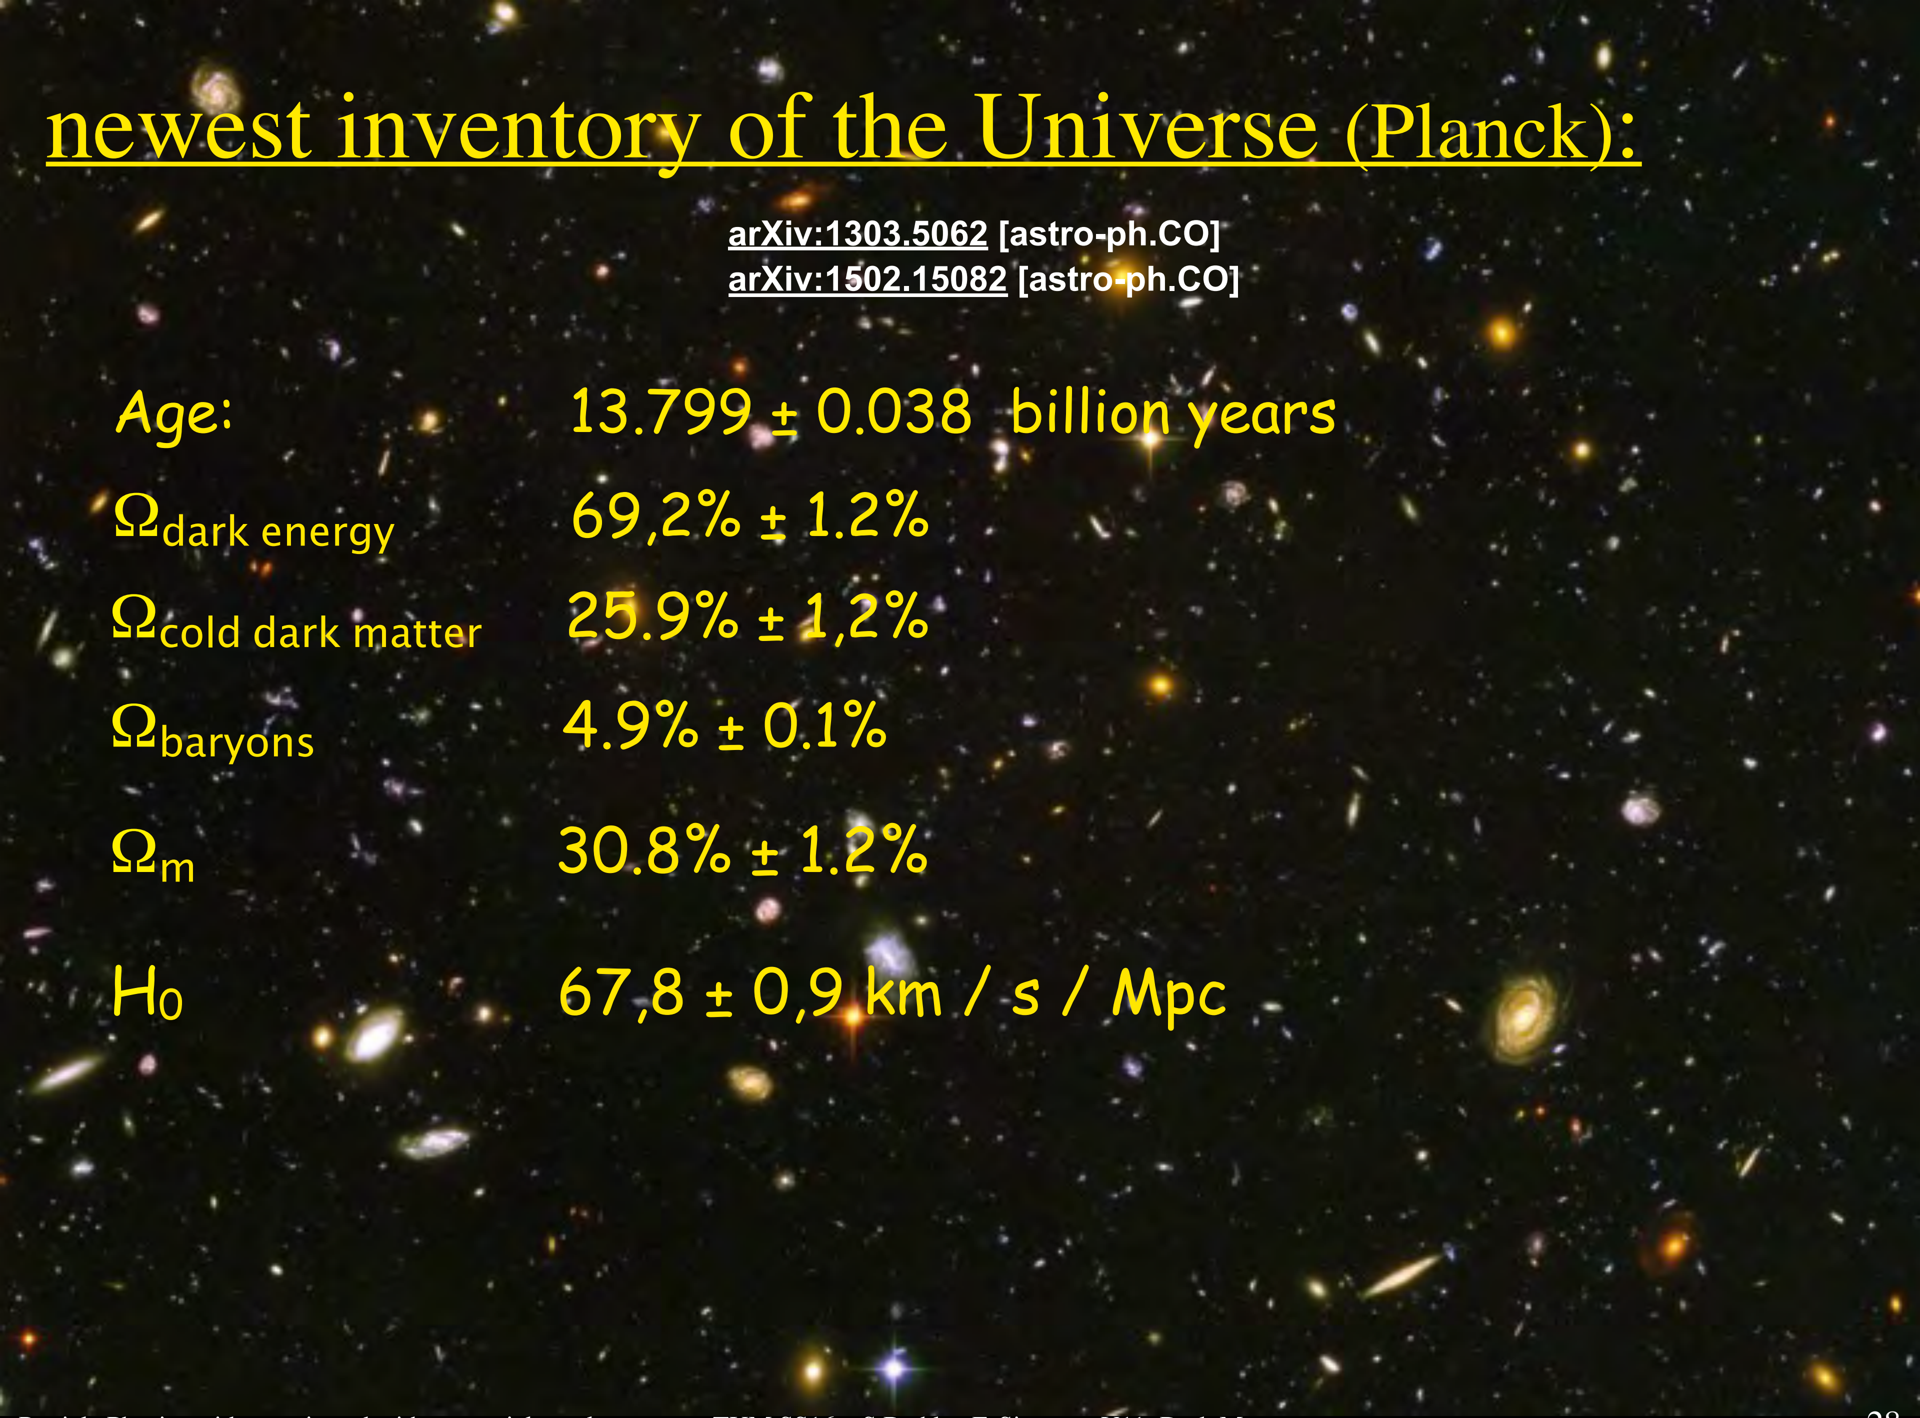
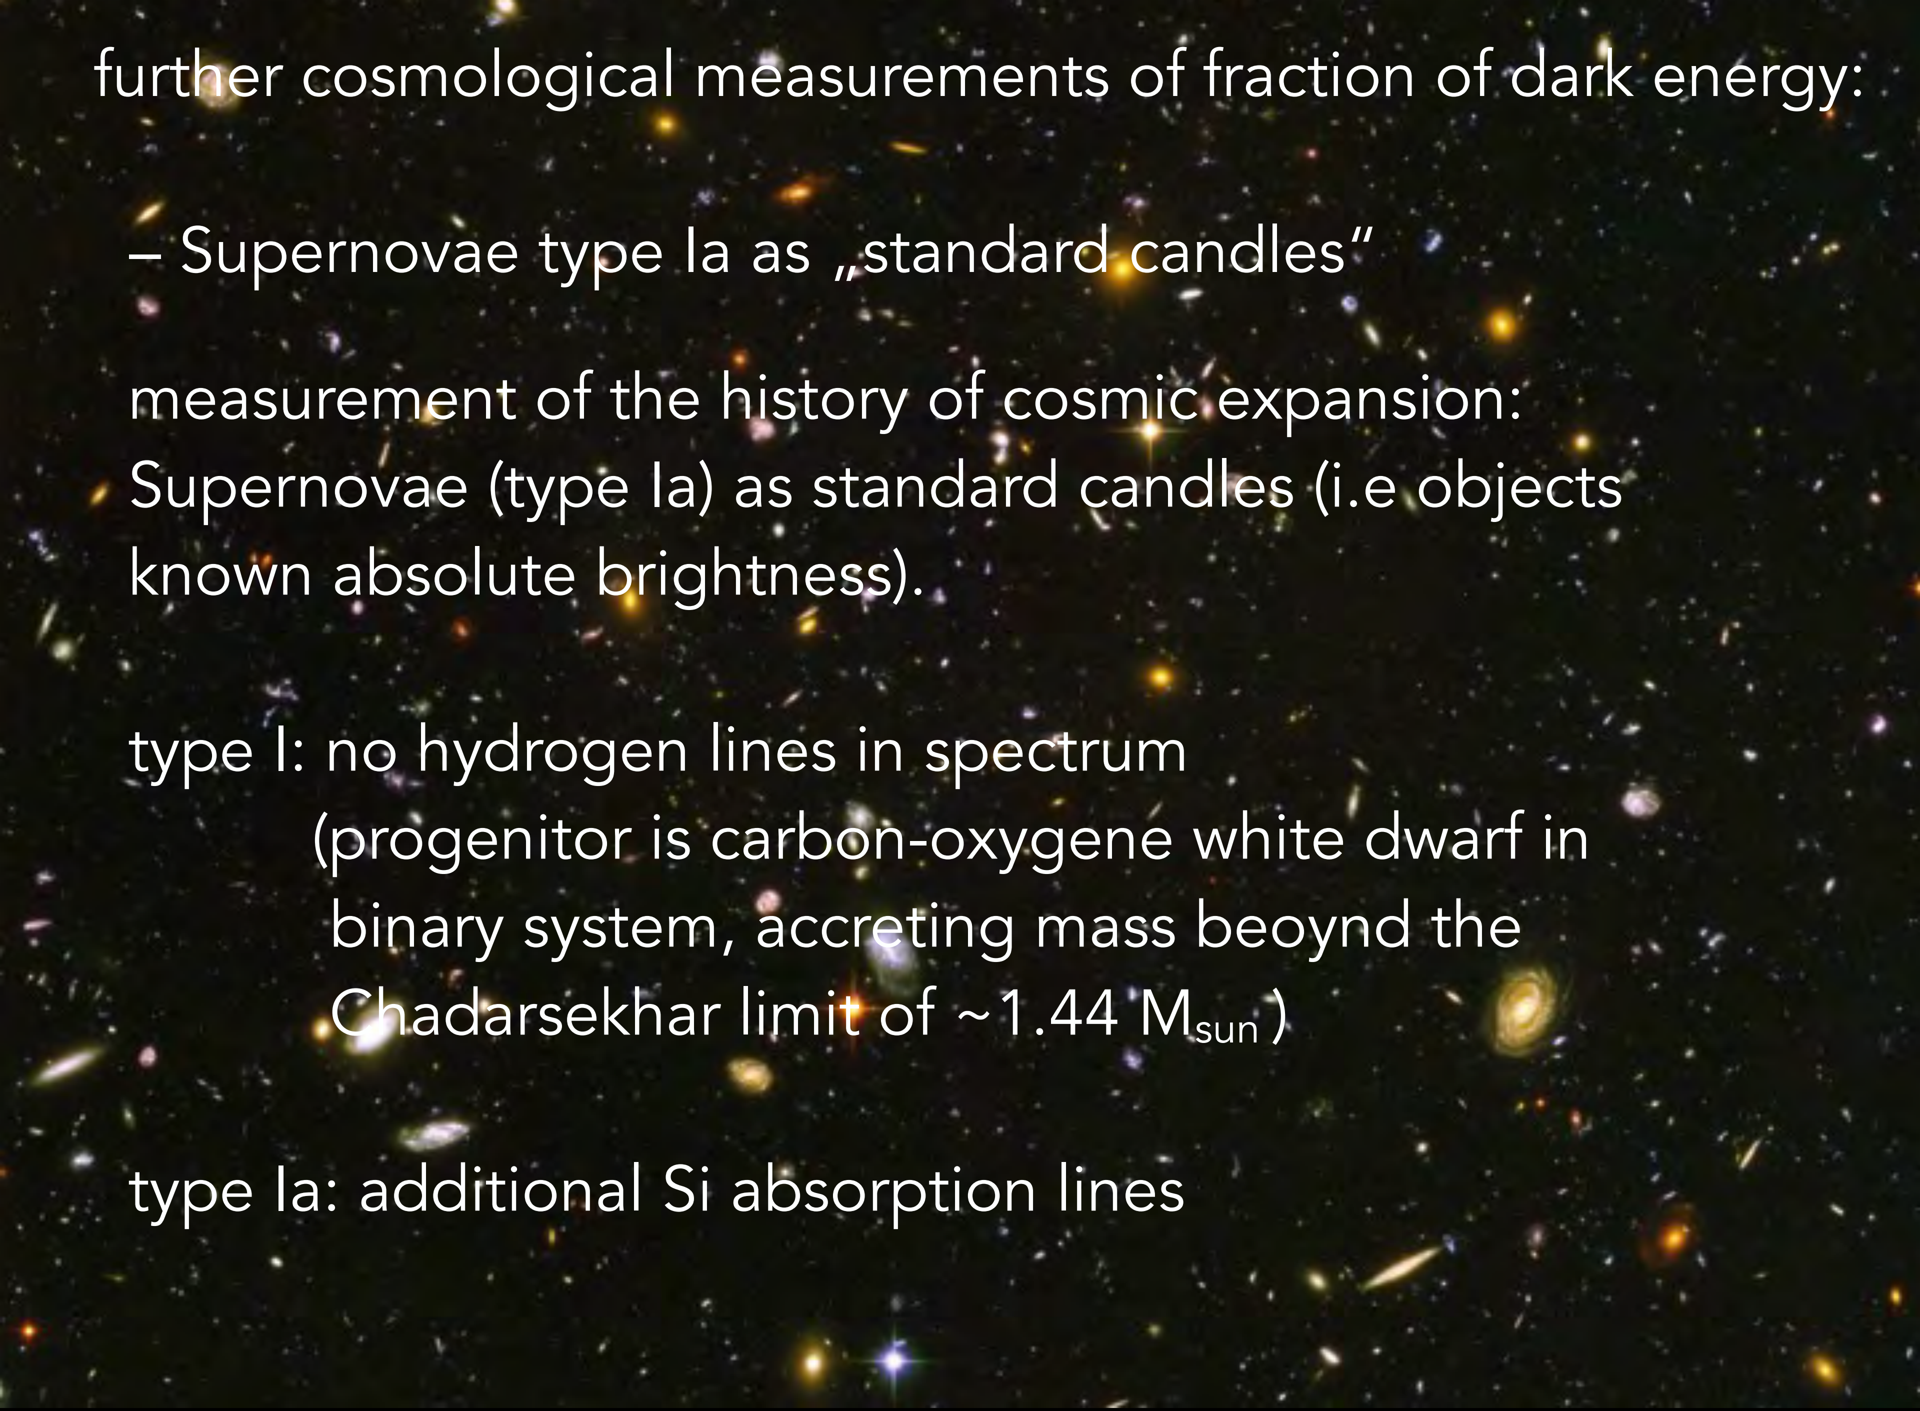
newest inventory of the Universe (Planck):



arXiv:1303.5062 [astro-ph.CO]
arXiv:1502.15082 [astro-ph.CO]

Age:	13.799 ± 0.038 billion years
$\Omega_{\text{dark energy}}$	69,2% ± 1.2%
$\Omega_{\text{cold dark matter}}$	25.9% ± 1,2%
Ω_{baryons}	4.9% ± 0.1%
Ω_m	30.8% ± 1.2%
H_0	67,8 ± 0,9 km / s / Mpc



further cosmological measurements of fraction of dark energy:

– Supernovae type Ia as „standard candles“

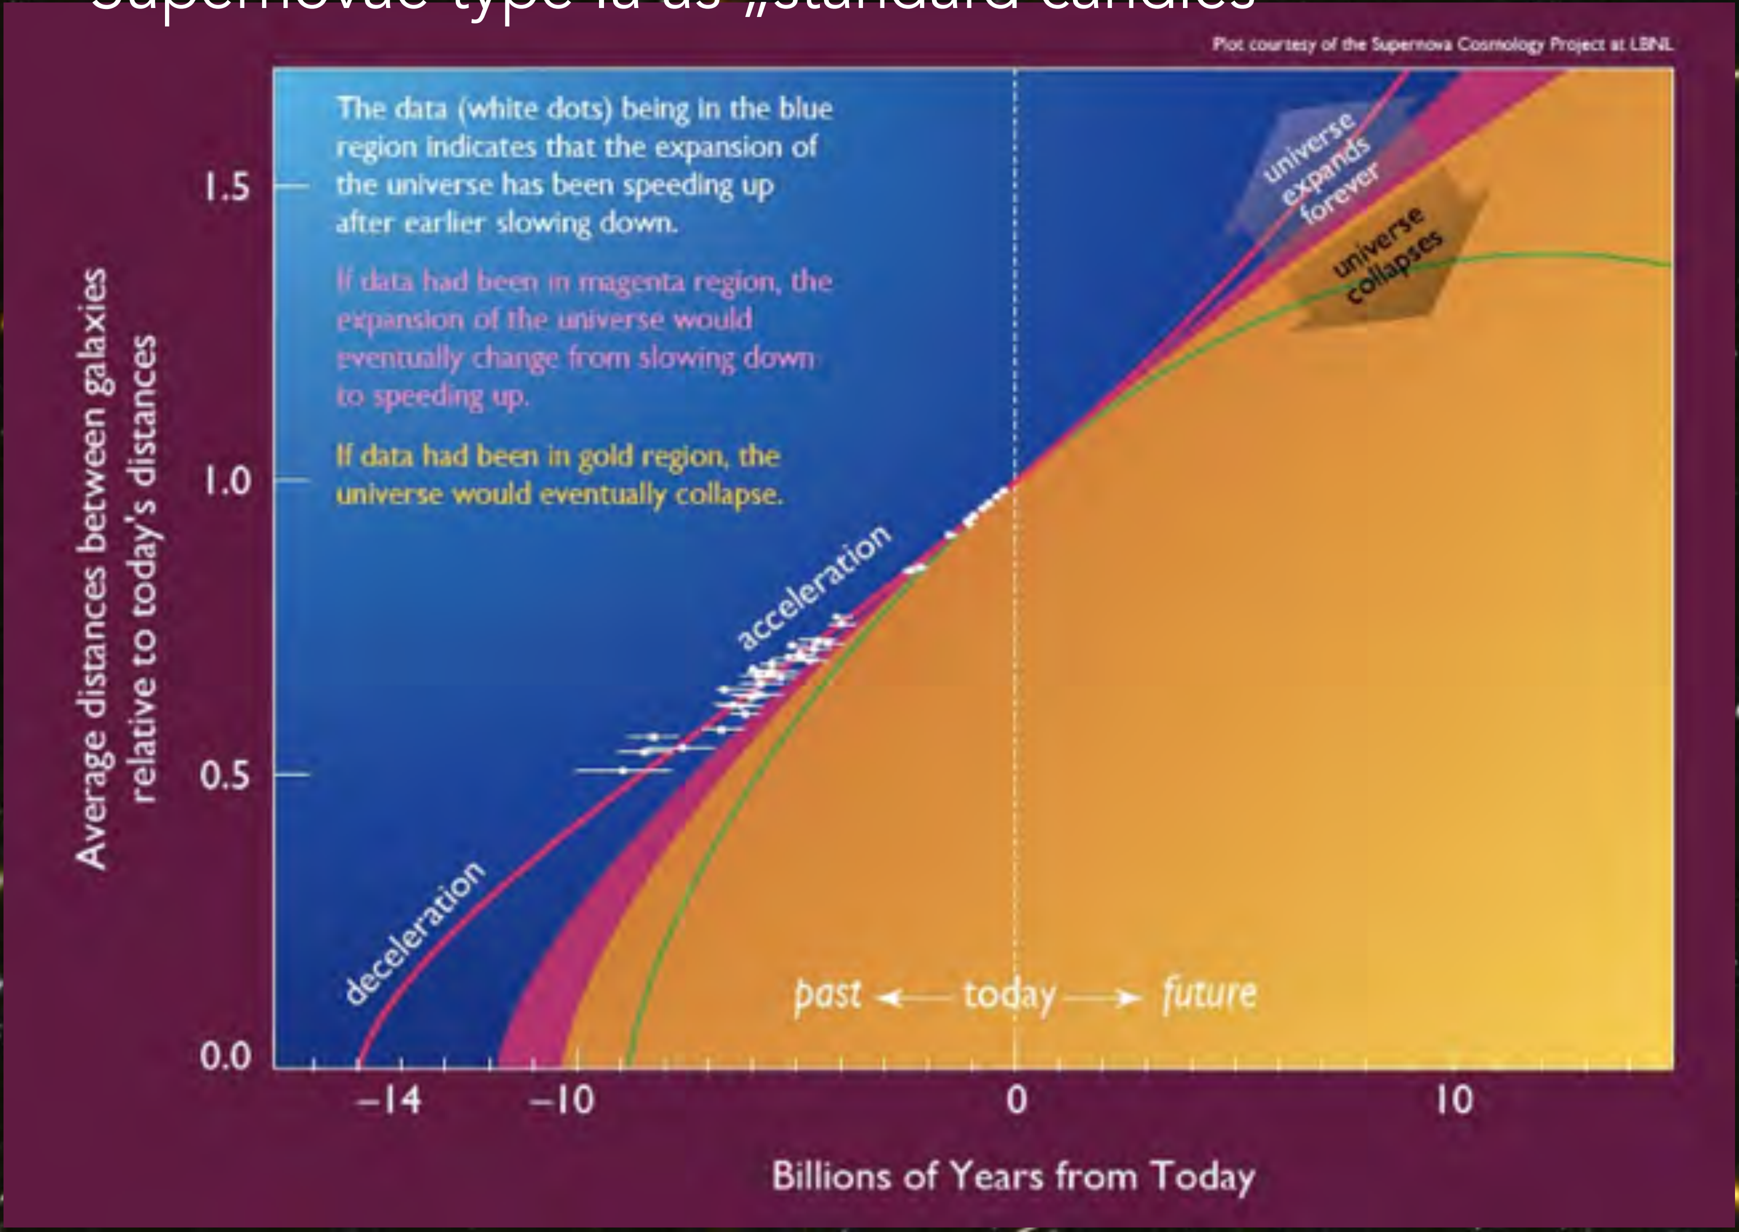
measurement of the history of cosmic expansion: Supernovae (type Ia) as standard candles (i.e objects known absolute brightness).

type I: no hydrogen lines in spectrum
(progenitor is carbon-oxygene white dwarf in binary system, accreting mass beoynd the Chadarsekhar limit of ~1.44 M_{sun})

type Ia: additional Si absorption lines

further cosmological measurements of fraction of dark energy:

– Supernovae type Ia as „standard candles“



Plot courtesy of the Supernova Cosmology Project at LBNL

The data (white dots) being in the blue region indicates that the expansion of the universe has been speeding up after earlier slowing down.

If data had been in magenta region, the expansion of the universe would eventually change from slowing down to speeding up.

If data had been in gold region, the universe would eventually collapse.

CMB: Cosmic Microwave Background
(WMAP)

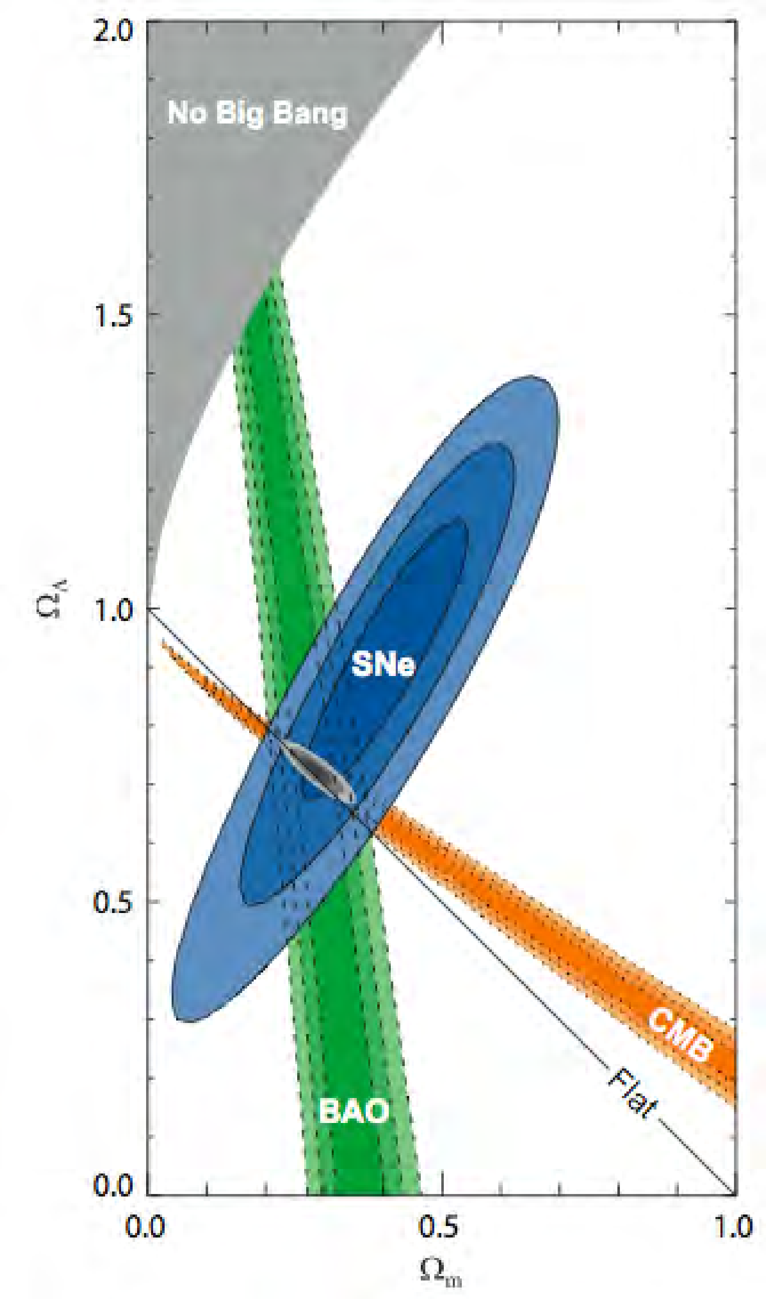
BAO: Baryon Accustic Oscillations
(aus Sloan Digital Sky Survey
der Galaxien)



general candidates for Dark Matter (particle physics):

- HDM: massive Neutrinos
  - „hot“: relativistic; would wash out primordial structures (too) rapidly to explain today’s structure

- CDM: Axions, SUSY-WIMPs
  - „cold“: massive and non-relativistic; preserves primordial structure.

- Dark Energy: … no clue in (exp.) particle physics… !

Supersymmetry (SUSY)

- provides cancellation of divergent radiative corrections –> solves hierarchy problem

- postulates symmetry between fermions und bosons:
  new fermion- (boson-) partners for all known fundamental bosons (fermions)

particles	**Spin**	**SUSY particles**	**Spin**
Quark Q	1/2	Squark $\tilde{Q}$	0
Lepton l	1/2	Slepton $\tilde{l}$	0
Photon γ	1	Photino $\tilde{\gamma}$	1/2
Gluon g	1	Gluino $\tilde{g}$	1/2
$W^{\pm}$	1	Wino $\tilde{W}^{\pm}$	1/.2
Z^0	1	Zino $\tilde{Z}^0$	1/2

- Higgs structure in Minimal Supersymmetric Standard Model (MSSM):
  2 complex Higgs-doublets (8 free scalar parameters) –> 5 physical Higgs fields:
  $H^{\pm}$, H_1^0 , H_2^0 , A^0 . consistency requirement: $M_{H_1^0} \leq 130$ GeV

- gauginos ($\tilde{\gamma}, \tilde{W}^{\pm}, \tilde{Z}$) mix with higgsinos and therefore result in
  4 *charginos* ($\chi^{\pm}_{1,2}$) und 4 *neutralinos* ($\chi^{0}_{1,2,3,4}$)

Supersymmetry (SUSY)

- 124 free parameters (!!) to describe masses and couplings of all SUSY particles; one of these: angle β, with tan(β) = v_1/v_2 . Only known constraint: $(v_1^2 + v_2^2) = 246\ \mathrm{GeV}^2$

- new conserved quantity: "R-parity": $R = (-1)^{3(B-L)+2S}$ (B, L: Baryon-/Lepton-number; S: Spin); R = +1 for normal matter particles, R = –1 für supersymmetric sparticles

- if R-parity conserved:
  - SUSY particles are produced in pairs
  - SUSY sparticles all decay into "lightest Susy Particle", LSP, which itself is stable.
  - cosmological arguments: LSP carries no electric and no colour charge <–> only weak and gravitat. interactions!
    –> in particle reactions, leads to missing energy (like neutrinos).

- Supersymmetry with masses of O(1 - 10 TeV) leads to change of energy dependence of coupling constants, such that "unification" occurs at $E \sim 10^{16}$ GeV
  –> proton lifetime >> 10^{32} years (beyond current experimental sensitivity) within SUSY-GUT.

- LSP is main candidate for Cold Dark Matter (CDM).

Search for Dark Matter

- direct:
  - – Large Hadron Collider ... (direct production and investigation of its properties)
  - – Search for WIMP* scattering in cryo-detectors
- indirect:
  - – WIMP pair annihilation inside Earth, Sun, centers of galaxies (into 2 photons, or Neutrino-Antineutrino; neutrino-telescopes as ICECUBE; cosmic ray exps.)
- furthermore:
  - – search for non-luminous, baryonic matter (MACHOS, massive compact halo objects)
- primordial black holes ...?

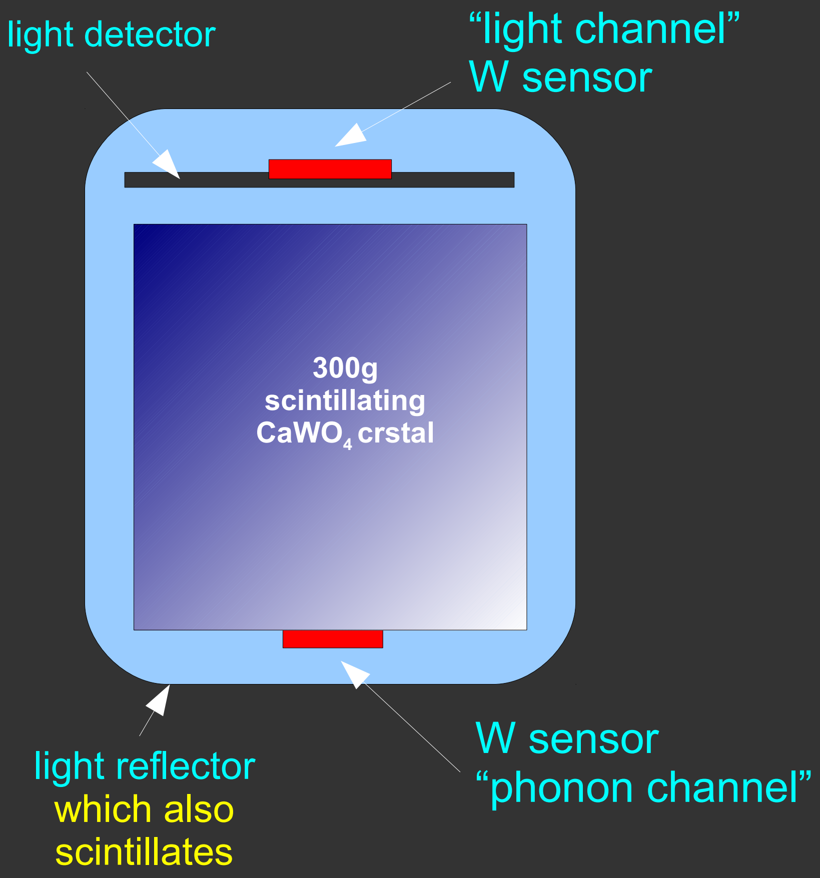
CRESST Folien von F. Pröbst

CRESST Detectors



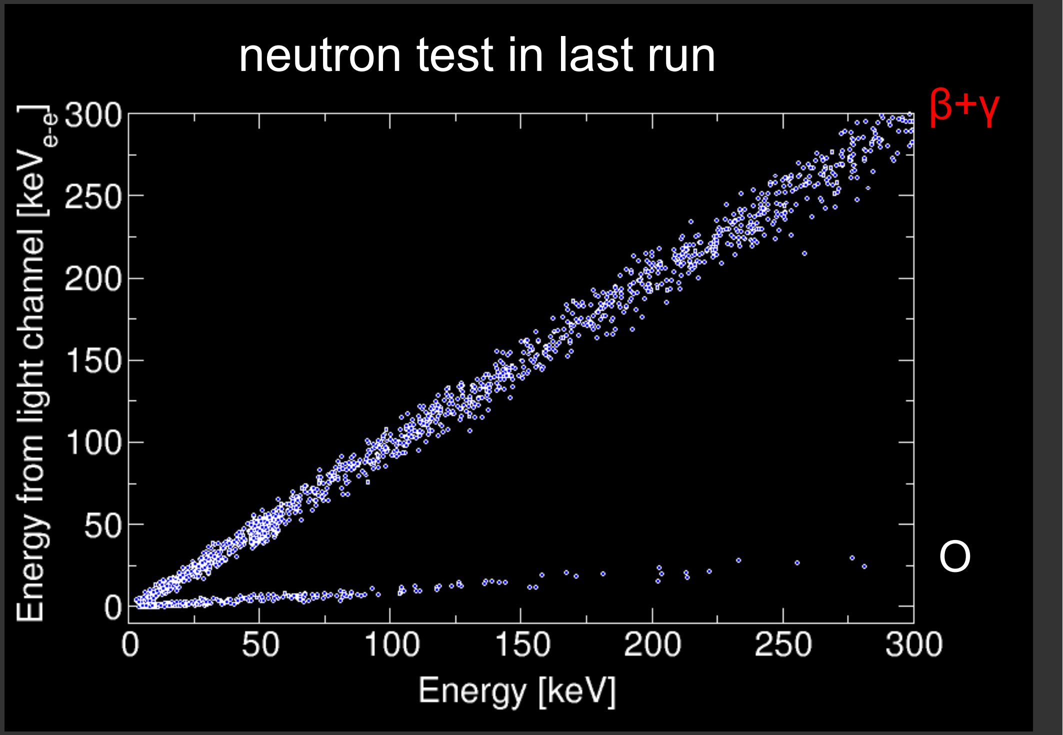
light detector

“light channel” W sensor

300g scintillating $CaWO_4$ crstal

light reflector which also scintillates

W sensor “phonon channel”



→ Phonon channel measures deposited energy with sub keV resolution and accuracy

→ Light channel serves to distinguish types of interaction

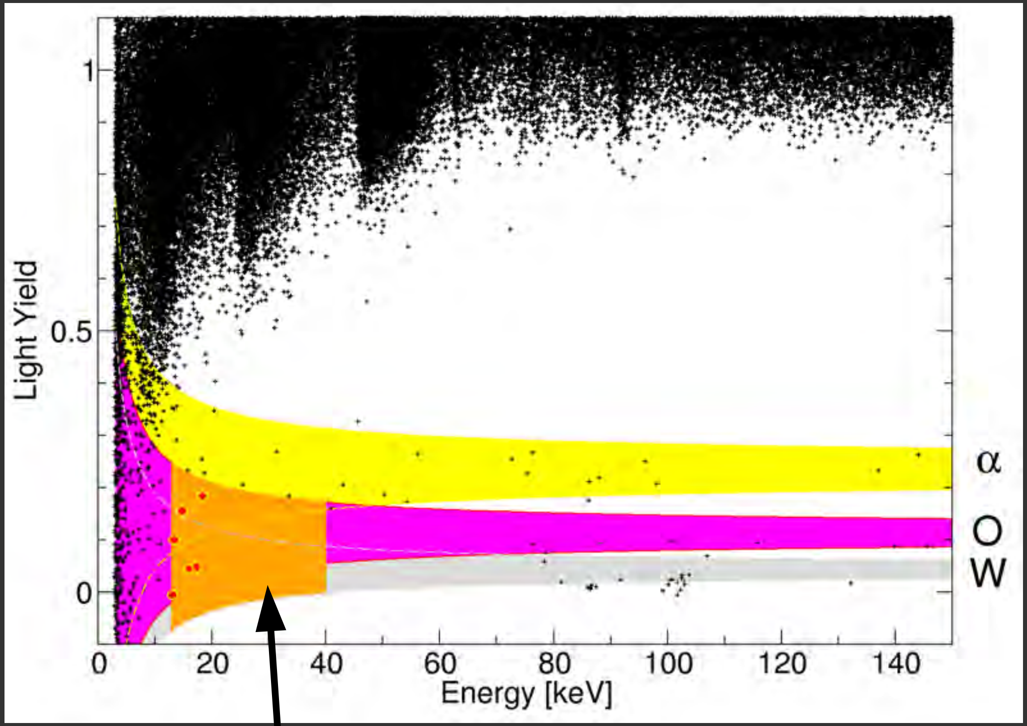
→ Types of recoiling nuclei distinguished by different slopes in energy-light plane

Discrimination of Event Types

$$Light\ Yield = \frac{E_{light}}{E_{phonon}}$$

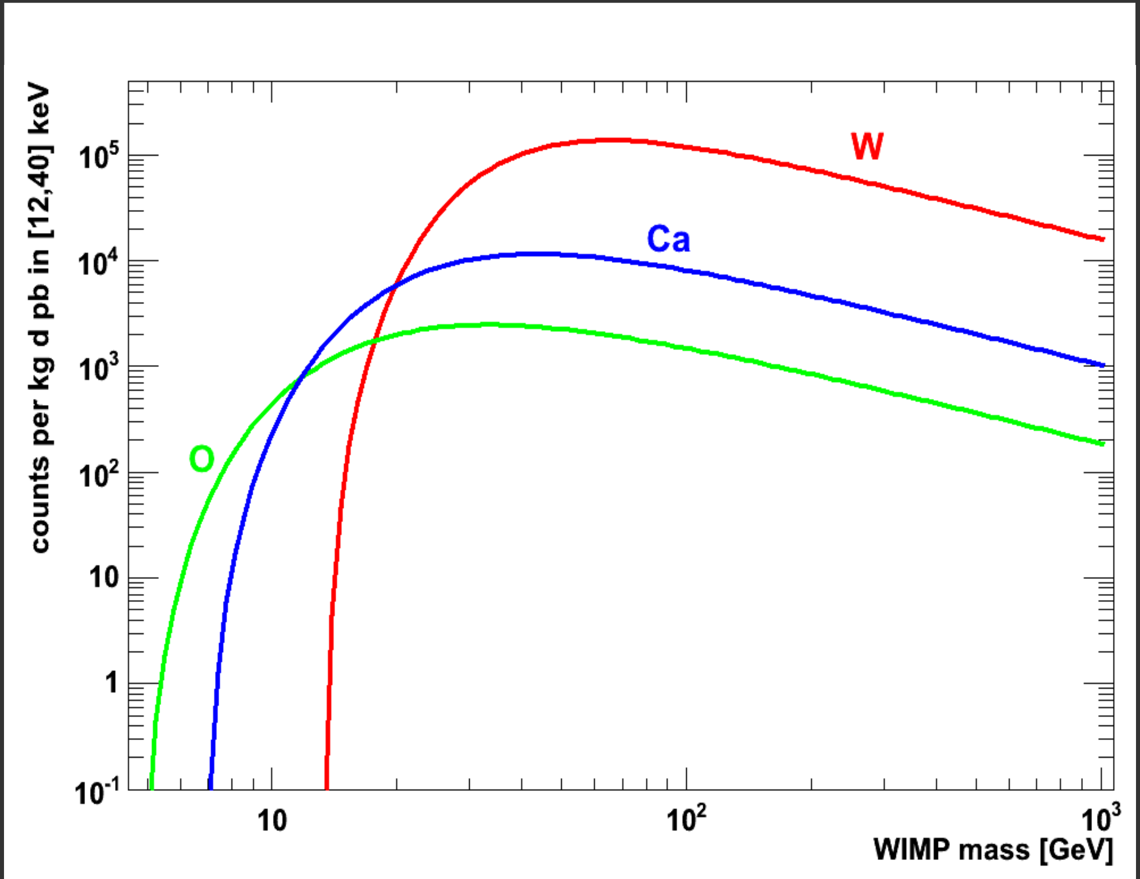
Event types characterized by different light yield

- efficient discrimination of nuclear recoils from β/γ-background
- WIMP signals expected in nuclear recoil bands



WIMP search region ROI includes O, Ca, and W bands

Types of Recoils in $CaWO_4$



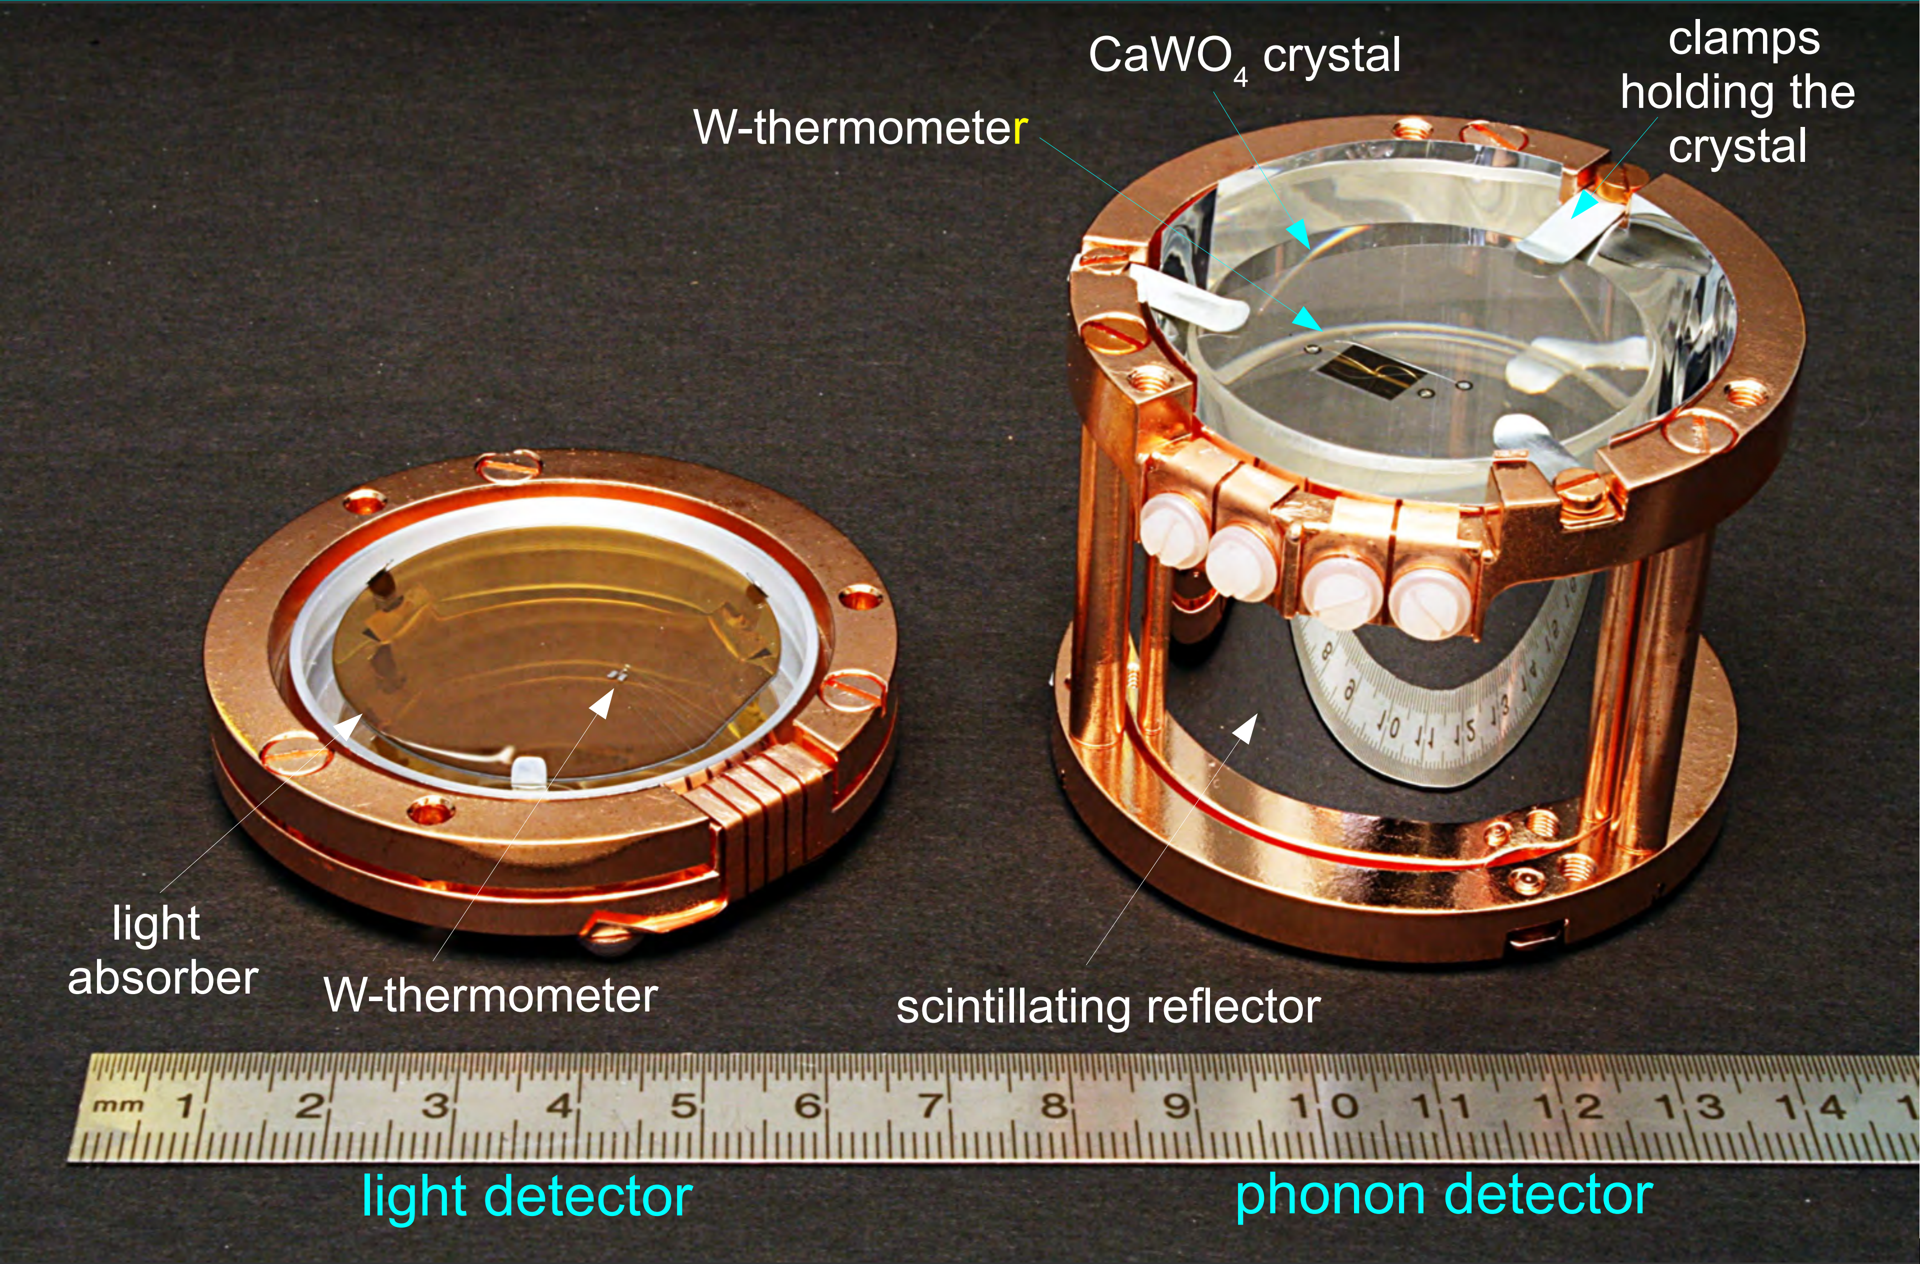
Assuming:

- $\sigma \propto A^2$
- detection in 12 to 40 keV range

- For M<10 GeV only oxygen
- Calcium important around 10 GeV
- Tungsten dominates at larger WIMP masses due to $\sigma \propto A^2$

→ type of recoils, together with the recoil energy spectrum, offers very detailed information on mass of possible WIMP

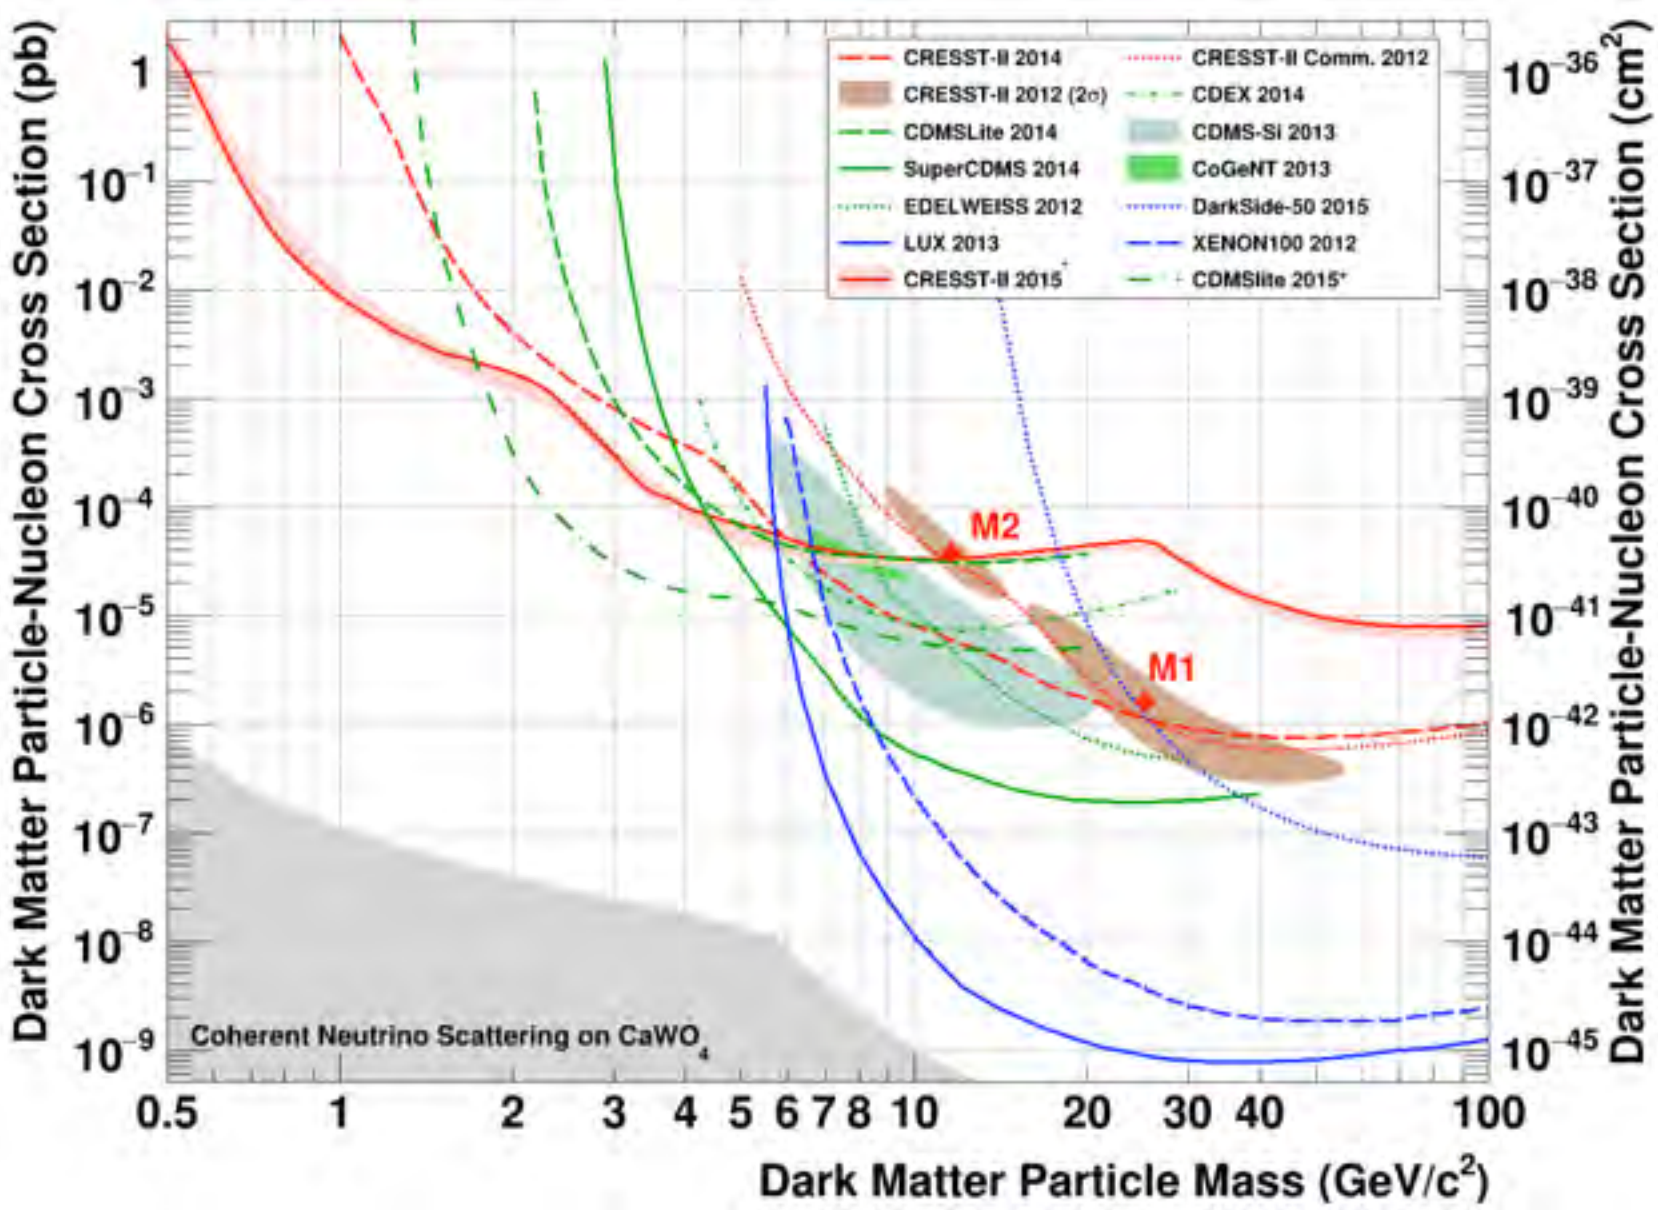
300 g Detector Module



light detector

phonon detector

Status of direct DM (WIMP) Searches



Summary

- non-baryonic Dark Matter (and Dark Energy) dominate mass-/energy density of Universe (~95%)
- Evidence for DM: from rotation of galaxies, structure formation, granularity of cosmic microwave background, ...
- only small contribution of hot dark matter (e.g. Neutrinos)
- candidates for cold dark matter: (SUSY) WIMPs, Axions,....
- indirect search: e.g. cosmic WIMP Annihilation; direct search: WIMP scattering in cryo detectors; LHC; ....
- nature of Dark Energy can only be studied by cosmological (astrophysical) means
