sw_en_out

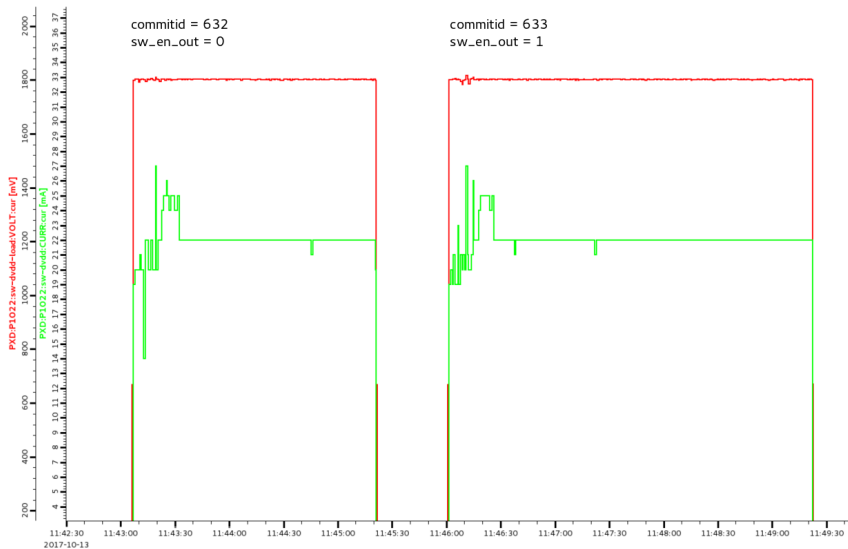

sw_en_out at the DHP enables the serial control lines to the switchers

- should only be enabled for the DHP which is connected to the switchers
- should not be enabled before the switcher sequence is uploaded (with not configured DHP memory sw-dvdd goes into current limit)

ways to ensure this

- set sw_en_out = 0 in the commit (not the case in the templates)
- ignore the PV from the commit in the DHH Sequence (implemented from epics-ioc-dhh-sequence-0.2.4 on)

Power up of W47_IB with different commits

sw-dvdd current is not in the current limit for both cases.

Power up of W47_IB with different commits - zoom

A zoom-in shows a bit higher fluctuation where $sw_en_out = 1$.

Power up of W47_IB with different commits - multiple times

For more statistics the power-up was executed several times.
There is no difference in current consumption or voltage fluctuation.
sw-dvdd stays in ± 20 mV.

Power up of W47_IB with different commits - multiple times

Two times the power up got stuck.

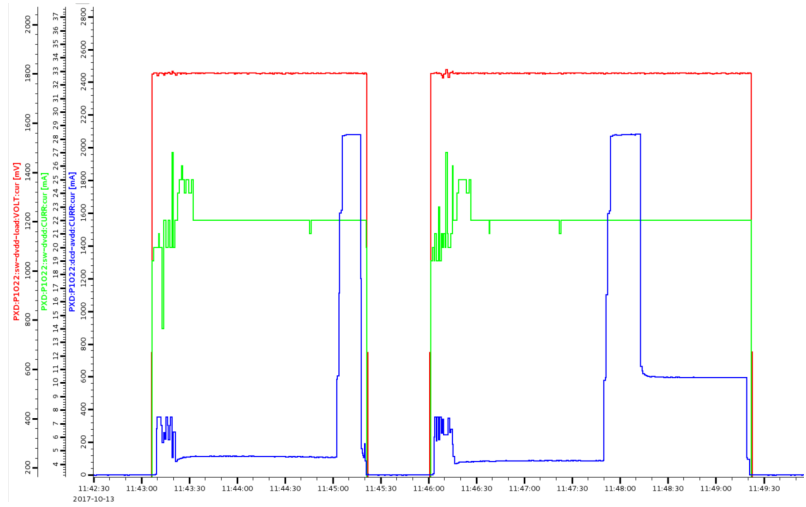

The dcd-avdd current shows that the analog parts of the DCDs were not enabled.

sw_en_out was not set back to 1.

When this occurs again, we have to see were exactly the power up sequence stops.

Power down of W47_IB - DCD1 not turned off

The power down sequence got stuck after trying to disable the analog part of the DCDs. Only a second, manually executed "Write Global Shift Register" set the DCD1 off as well.

Power down of W47_IB - DCD1 not turned off

The analog parts of the DCDs are enabled with a short pause in between. The disabling is done for all at once.
