TauRec

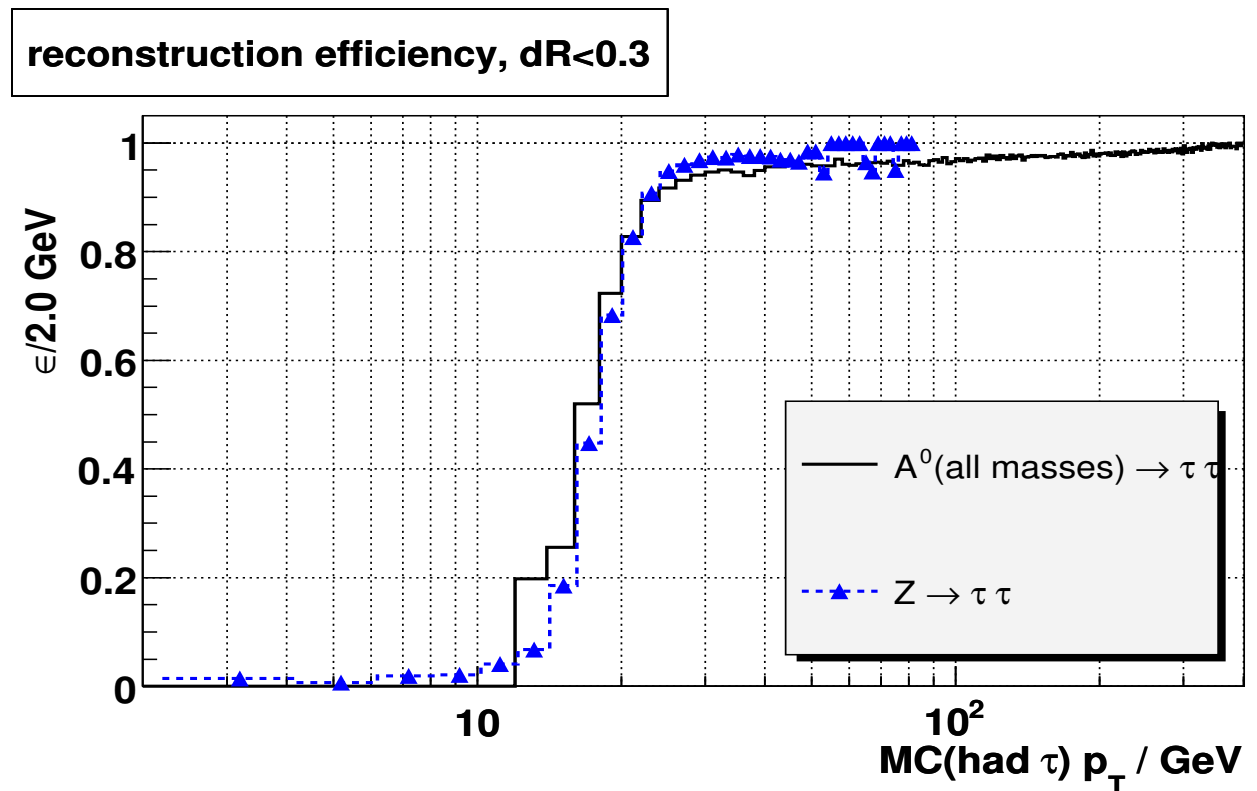

Michael Heldmann
Universität Freiburg

- **Reconstruction**
- **Calibration**
- **Identification**
- **Running with TopoClusters**

TauRec (reconstruction)

- TauRec starts from CombinedClusters
- CombinedClusters are clusters from a sliding window algorithm
- Current settings for seeds give the following reconstruction efficiency (e.g. the probability for a mc true hadronic tau to have a reconstructed cluster within $\Delta R < 0.3$)
- Because of this turn-on already on reconstruction level tauRec is (if seeded by CombinedClusters) only suitable for tau with $p_T > 20 \text{ GeV}$
- TauRec can be seeded (only a change in the jobO needed) by any collection of vectors, e.g. Jets, tracks, or topoclusters

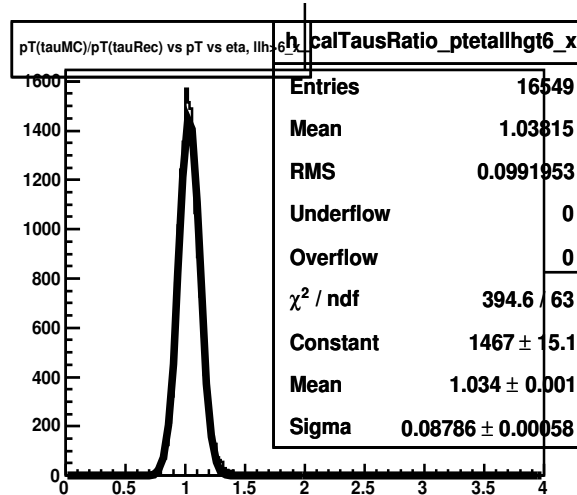

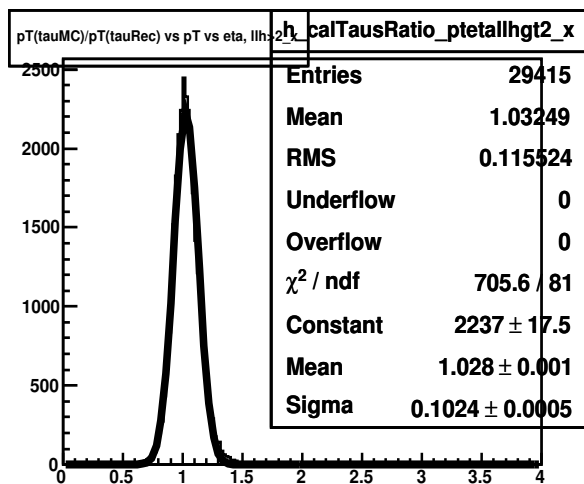

TauRec (reco open questions)

- Other seeds have never been thoroughly investigated for tauRec
- Taus seeded by jets (probably cone?) from TopoClusters could be interesting
- The TopoCluster algorithm could act as a good noise suppression, both for the calibration and for identification
- One may also look for sub-TopoClusters in such a jet (mainly for very low p_T taus), using the categorization into EM and HAD Clusters to separate the Pi^0 from Pi^+ clusters
- This may also allow new ID variables as e.g. Inv. Mass between track(s) and EM subcluster(s)
- It may also improve the reconstruction efficiency for low p_T taus in general, allowing for potentially more spread out energy

TauRec (calibration, current)

- Noise cut: take only cells which are above $2 \cdot \sigma$ (electronic noise for the cell)
- This cut is applied to cells used for identification and for cells used in calibration
- Calibration is done using an H1 style algorithm, weights are the ones obtained for jets
- A p_T and η dependant correction factor, specific for taus, is applied after the cell level H1 calibration
- For CSC with old weights the calibration is still OK (after fixing the sampling fraction difference in the tile), but not perfect

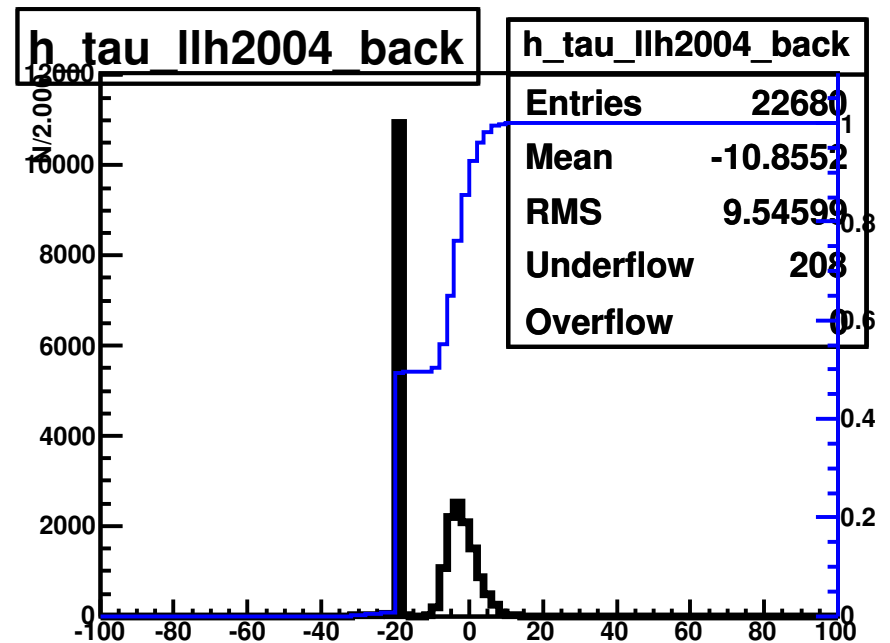

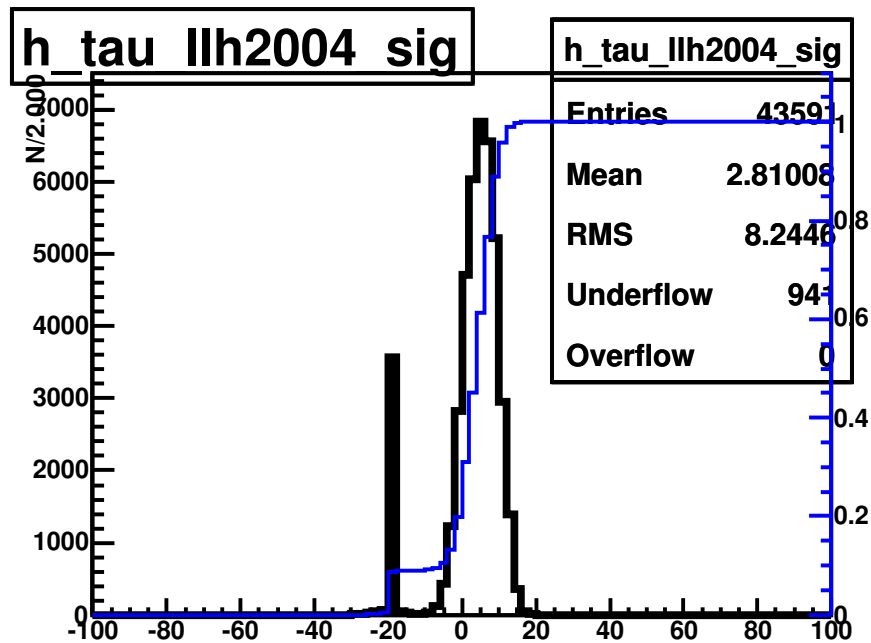

TauRec (calibration, open questions)

- H1 style Calibration should have weights trained for taus
- They should be optimized separately for different tau types (e.g. Pi^+ , $\text{Pi}^+ + \text{Pi}^0$, 3Pi^0 , ...) as far as these can be separated
- It depends on the ID cuts chosen on the level of a few percent change in the mean, because one selects e.g. cleaner tau candidates
- It obviously depends on p_T and η , and the weights might require a smaller η binning than for jets, because one could potentially resolve smaller details given the narrower energy deposit
- At the moment it generalises between samples only at the few % level (e.g. If you go from one sample, perfectly calibrated with a fudge factor in p_T and η to another sample you still might see $\sim 2\%$ percent offset, before ID cuts, less after ID)
- The local hadron calibration provided with the TopoClusters should certainly be tried out, expecting to make a physics object calibration on top of that
- The last point might improve automatically with the points before
- **Energy flow type of treatment is covered by Elzbieta + tau1P3P**

TauRec (identification)

- ID variables show some funny features if plotted directly, one has to remove the bad cluster seeds by hand, e.g. $\text{tau_et} \neq \text{nan}$, $\text{tau_et} > 15 \text{ GeV}$
- ID dropped somewhat on CSC because of problems with the seeding clusters. We suspect that a splitting and merging was introduced which is not correctly treated in tauRec. This has to be understood and fixed.
- **Conclusion: taus are very sensitive to seeding, so using TopoClusters could yield a more stable seed for the taus**

TauRec (identification, open questions)

- Should the identification variables also be calculated using only cells from TopoClusters ?
- Some noise suppression is certainly needed (at the moment simple cut $E_{\text{cell}} > 2 \cdot \sigma$)
- More sophisticated treatment of taus in the calorimeter could be promising like
- Searching for EM subclusters could be done separating HAD and EM subcluster
- One could use TopoCluster in EM only to find π^0
- and in HAD+EM (for the hadronic subshower)
- or use even more specialized information e.g. in the eta-strip layer only
- also for very low p_T taus the strategy may be based more on finding individual components of the tau, for these also in combination with tracks

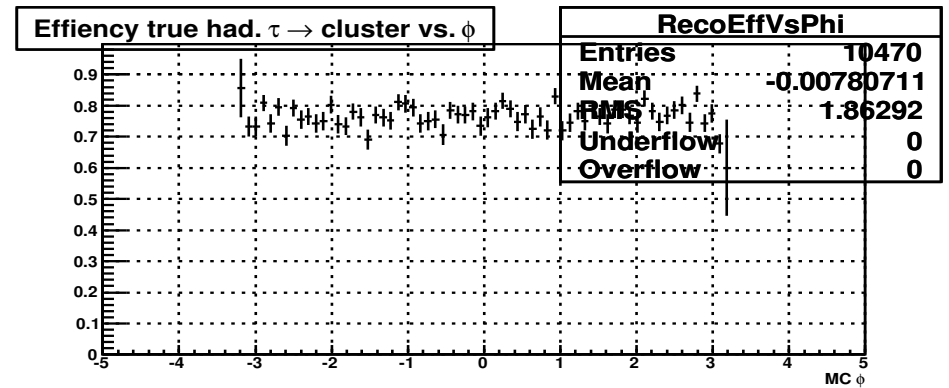

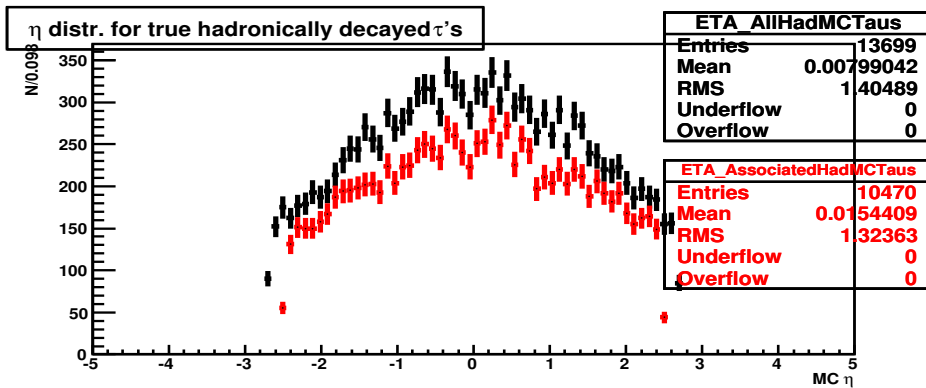

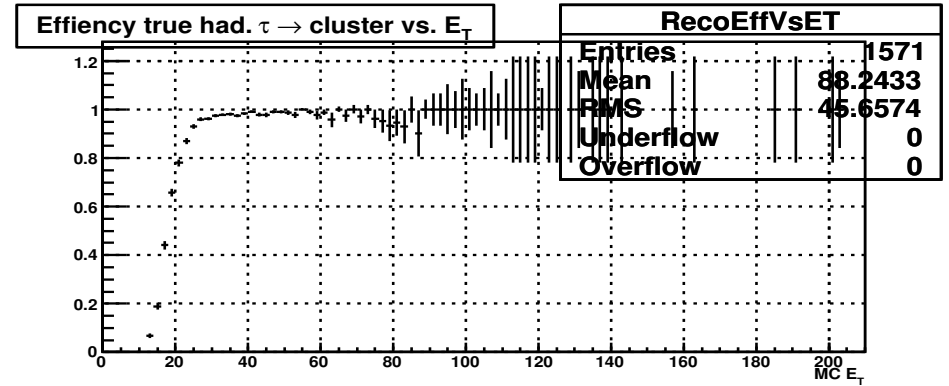

TauRec with TopoCluster

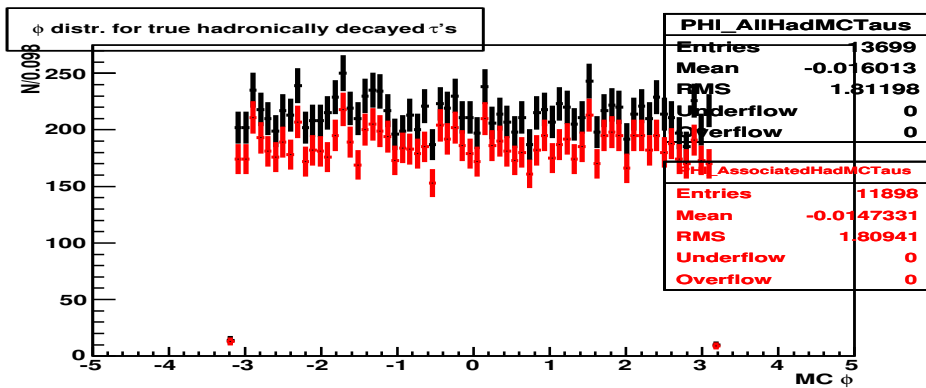

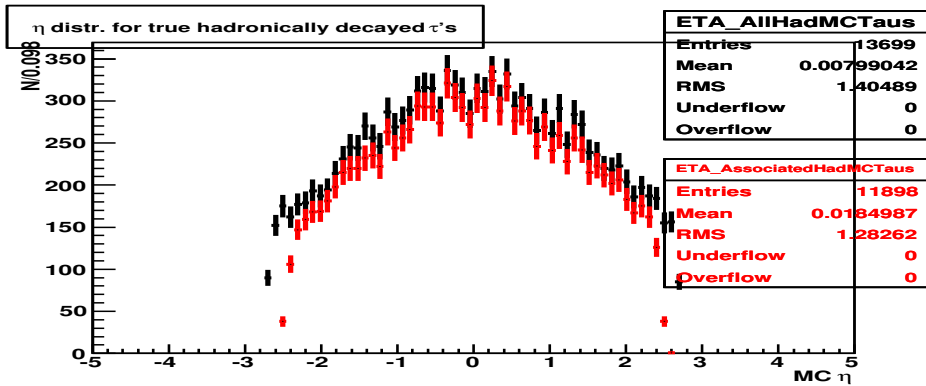

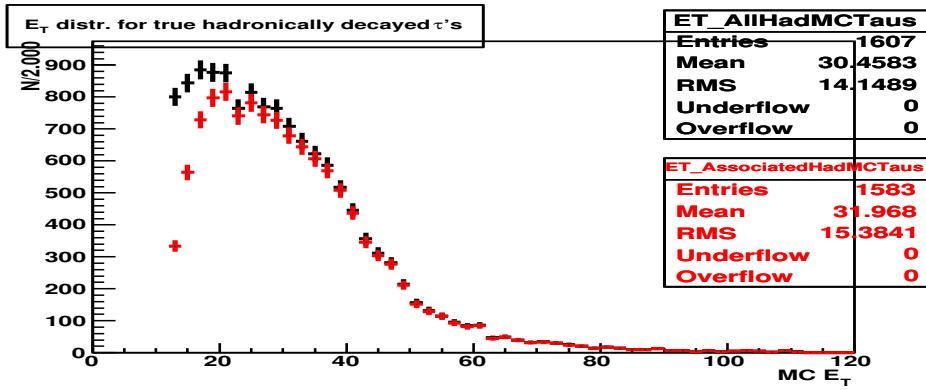

- In tauRec-02-03-05-08 and on the tauRec Wiki page I provided some example jobO for running the existing ConeClusterJet and using these jets as seeds for taus. The resulting CBNT has both normal tauRec and tauRecTopoCluster variables.
- Cells are already taken from TopoClusters, for Calibration and for ID variables
- missing:
 - The correct treatment of cell overlaps between TopoClusters (in tauRec)
 - Calibration tool to make use of the local hadron calibration missing
 - TopoCluster specific tools are missing completely (monitoring, additional variables, ...)
- This is just a first try to get things going ! Hubert's group (Susanne et al) showed interest to contribute to this topic. Maybe already results for Barcelona ?

BACKUP SLIDES

General open questions

- Events with pileup (not even low lumi) have never been studied
- $Z \rightarrow \tau\tau$ not only to get PDFs is still not thoroughly studied in fullsim (Asen Christov is going to do this for his Ph.D.)
- A clear strategy for how to validate (“certify” as in D0) a certain algorithm for tau ID is missing
- A systematic monitoring of the input quantities with e.g. RTT also with respect to data taking should be established
- Current strategies for selecting “calibration” events would require a rather good understanding of MET, maybe we should try to decouple that (e.g. no collinear approximation for $Z \rightarrow \tau\tau$ if possible)
- Maybe later we want to improve our understanding of 3 prong decays. Questions of tracking (e.g. For high p_T where it's difficult to separate tracks) or secondary vertexing for taus are still not thoroughly understood (a simple sec. Vertexing is done in tauRec but not fully studied)
- Very low p_T taus are quite difficult (< 10 GeV), what use cases are there ? What would be the best strategy to reconstruct and identify them.

TauRec (identification, open questions)

- Retraining the old likelihood with ROME data improved performance on ROME data by 5-20% in rejection (depending on pT)
- A retraining on CSC might be feasible (after figuring out the problem with the seeds)
- A 2 dimensional likelihood might be interesting, given a good smoothing is used
- Retraining likelihood for different tau type separately might be interesting, but first attempt did not yield a significant improvement (also the available statistics might have been the problem (less pT bins possible))
- Asen is looking into electron \leftrightarrow tau separation
- A neural network is also available in tauRec from Kamal, but only for a small pT range (17-35GeV)
- Many more ID variables than the usual ones are implemented in tauRec, mostly copied from D0
- Some are promising but of course highly correlated with the normal variables

TauRec (identification, CSC)
